It's worth remembering that this would make the anode current read high when the radio is correctly adjusted - so if you set it for 200mA then you would actually be getting a much lower current through the valves.

I found that ordinary plastic trimmers were far too soft, so I made one out of an acrylic knitting needle chopped to about 6" long with the end filed to a screwdriver point.

Forgot to mention - with *all the power off* and using a metal screwdriver with a plastic sleeve up most of the shaft (same one as I use for working on live connection boxes) I spun the neutralising cap a few times in both directions to break the stiction. It was very very stiff to turn initially, probably because it needed a thin smear of 30-year-old grease spread around the shaft bush.

Gordon

Hi Guys. If you do much work on radios it might pay to get a
fiberglass screwdriver. Its stiffer than the plastic tuning tools,
and the end can easily be filed to whatever size/shape you need.

TTYL

20730. cooling

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-01 16:20:56 UTC
From: wb4mnk@bellsouth.net
Topic: 20730 Message: 20730

I am interested in any ideas about cooling the TS-830S more efficiently. Has anyone tried a different fan with good results ? I use the TS-830S on digital modes at a lower power up to 30 watts and it seems to run a little hotter than I like. Any ideas and suggestions will be appreciated.

73,
Art

Well, I have not tried this on a Hybrid but I will share info about cooling that is applicable from building lots of high performance computers.

You can add a fan with a higher CFM but it will most likely generate more noise. Also with the higher CFM and the current venting you will generate a higher, more negative air pressure thus acting like a vacuum cleaner. This will generate more noise too but it will also cause more dust to accumulate which in turn will cause more heat. Usually when I build a hotrod PC I try to have more air going in than going out for a positive air pressure. This keeps everything cool and lowers the dust buildup...also less fan/air noise.

You might look at it like putting on larger carburetor jets, with a higher flow intake and not changing the exhaust on a motor.

Now your best bet maybe to get some perforated grate metal and form a new final cage cover. This would allow more cooler air to come in without upping the CFM of the fan.
I would not drill out the stock cage cover as it would begin to rust everywhere you drilled holes.

That also might change the stability/drift of the rig too. I have heard rumors that the 520's and 820's ran more stable by shutting off the fan. Not tested on my part and would not but thought i would add that in there anyways.

Regards,
Aaron

20733. Source for REMOTE plug

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-01 17:01:53 UTC
From: Jim
Topic: 20733 Message: 20733

Just got a ts-820 and want to start using it with my Ameritron AL-811H. Looks like I should be able to use the remote socket on the back of the radio. However, I don't seem to find a source for the male plug for the remote socket. Does anyone know of a source or substitute part for this?

The Ameritron is "open normally" on receive so looks like I should use pin 5 for the tip of the RCA plug.. and would it be pin 4 for ground?

From the manual and it shows the pin-out diagram of the remote socket with pin 1 being the one just to the right of the socket-notch. But is that orientation looking at the back of the radio or from the solder-pins on inside of the radio?

Thanks

I too, have a TS-830, which I run on SSB mostly wide open (full power ~100W) and I notice much less heating than I expected. My interpretation of this is that the original designers are smarter than I and "...if it ain't broke, don't fix it...". Therefore, until someone smarter than me has a definative reason to site, I will trust the original designers of the legandary Kenwood line (after all isn't this the reason "we" bought Kenwoods, even hybrids). I am not trying to pick a fight just voicing my thoughts, we still have freedom of expression left in this country the last time I checked.

Respectfully,

Chris...

I use my TS-520 for PSK31 running about 10W for licensing reasons (limit is 10W measured at the antenna end of the feeder), and it doesn't seem to get any hotter than when it's in receive, even on long overs.

I wonder how much of this "valve PAs aren't suitable for digital" is real and how much is "received wisdom"...

Hi Jim,
Radio Daze has them. Look for *PLG-8-P1 also, they have the Covers for them as well.
I just received two of the plugs with covers. Very Nice!

One fix is to just break off the base of an old 6146b tube. The pins fit the socket exactly. Then just wire it up as required. This is a bailing wire work around but does work.
To verify orientation just check with your multimeter. Pin 1 and 4 should be ground and pin 8 no connection.

Looking at the rear 8 pin socket, notice the notch. The pin to the lower "right" is pin 1. You can also fine the pin numbers by looking at the 8 pin octal socket from inside the rear panel. The pin numbers are printed on the "wiring" side of the 8 pin socket. You will need a flash light and a magnifying glass to see the numbers.

The cooling fan is NOT designed to keep the final's "cold" but to move heated air out of the final cage. If the final amplifier cage, components, including the driver and final tubes, are coated with dust, it doesn't matter how strong the fan it, the dust will act like a blanket and hold heat "in". Clean the final cage and fan as part of your normal scheduled maintenance. There is no need to add additional cooling to the hybrid final cage, the factory fan, as long as it is kept clean and lubricated, will do just fine. Excessive heating in the final can be reduced by stop pushing the final amplifier too hard (running max power output on every transmission)! Those few extra watts one may be squeezing out by pushing the daylights out of the final will only shorten the life of the final tubes and produce distortion and splatter, nothing more. The distant end will not even notice a difference in your signal strength if you are running 90 watts output or 110 watts output.

Hi,

You may find the HV electrolytic(s) need
replacement.

http://www.k4eaa.com/parts.htm

also good idea to try a new driver tube
before you replace the finals, keep the tube
for another radio where it may work fine.

Hi Mike,

I fulling understand but I was concerned about digital modes mainly during contesting. I never push my 830 at all and I guess that is one of the reasons it has given me such great service. My 830 seems to run warmer to the touch under these conditions than during SSB which makes sense but would like to keep it a little cooler. Thank you for your valid points.

73,
Art

20745. Wire Cut to PLL board on TS-830S

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-01 23:03:00 UTC
From: Gordon
Topic: 20745 Message: 20745

This is the second TS-830S that I have worked on in the last 2 weeks that has a wire cut going to the PLL board.
The wire is on Connector #2 and it is the #2 wire. It goes to the Counter unit connector 2 pin 9.
When this wire is cut, the display and bands are DEAD for 160, 17 meters and the bottom of 10 meters. Neither radio had a FIX crystal installed, but I wonder if this was some sort of CB Mod. Anyone have any clues WHY someone would cut this wire? The one I have now, the cut wire was wired to two of the unused portions of the FIX switch so you could open or close the circuit. very Strange.....

Hey guys. I have a TS-520s that is not firing up when the switch is turned on. I wired a new jones connector for it, and did check that I was getting power on the right leads (3 and 6, with 9 and 8, 7 and 10 jumpered per the manual). It also has the correct pin jumpered for the external VFO. Any suggestions?

Chris KQ6UP

When you plug in and switch on, what exactly *does* happen? Anything?
Nothing?

Gordon

Ok before I get jumped... its not my only Hybrid but it is my nicest one. It is near perfect and I need to sell it to purchase a new primary rig. I still will probably regret this and thought I would post it here before it goes to QTH then Ebay.

Asking $400 + Shipping for the following items.
Mint!!! Almost a 10, TS-520S with the original manual and box.
Perfect condition MC-50 Microphone
Extra set of brand new tubes ((2)JAN/GE 6146W & (1)GE 12BY7A)
2 Extra Meter Bulbs
2 Extra Feet
PayPal OK

PIC HERE: http://groups.yahoo.com/group/TS-520_820_530_830/photos/album/1267094731/pic/741451665/view?picmode=large&mode=tn&order=ordinal&start=1&dir=asc

The Kenwood numbers are different than the Jones plug numbering. They
are a mirror image of each other.

I will re-wire and try again.

OK, now it is working FB. I just had a CW QSO on 40m. Looks like it
needs an alignment though. CW is heard on both sides of the carrier at
almost equal magnitudes, so I suppose that it is sorely out of
alignment. Also, only able to get 15W out on CW. The mic I tried
provided T/R switching, but no modulation. Might be the
wiring/element. I also have an astatic D-104. Would this be a good mic
for it? However, I do not know the color code for the wires, and it has
no connector.

Thanks,
Chris KQ6UP

20756. 520SE Meter window

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-02 04:29:53 UTC
From: sv0xbq
Topic: 20756 Message: 20756

Hi Everyone,

Has anyone got a spare plastic window that fits over the meter and frequency dial on a TS-520SE ? Mines been damaged in transit.

Chris SV0XBQ

20757. Strange issue with the carrier controll

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-02 03:45:31 UTC
From: Christopher Maness
Topic: 20746 Message: 20757

When I am adjusting the carrier knob, it does not give me a carrier in the TUNE position unless I turn it all the way down. That ends up giving me about 50W on CW. When I had the carrier turned up, I was getting 15W on CW, and nothing on SSB (but that could be the mic because the radio is new to me). This seems backwards to what is supposed to happen.

Thanks,
Chris KQ6UP

Whats "a little hotter than I would like?" - traditionally, "if its too hot to touch, its too hot." (this idea has been resurrected in PC's, which , according to computer types, can run at blistering temperatures with no problems, at least during the warranty period.)

But seriously - if its more than comfortably warm, then
1.Clean/lubricate the cooling fan - easy to remove, 4 screws and a connector.
2.Remove the finals cover, use compressed air and blow out all the dust - if you haven't done these for a while, you will be amazed how much crap is in there -
3.Check your PA idling bias, not sure if its different from other Kenwoods, but 60ma rings a bell.
4.Is it well ventilated? - ie, its not at the bottom of a stack of other gear, piles of magazines etc on it - are all the ventilation slots clear and clean. (This includes the logbook slid under it) ...
And give us some before/after feedback - most modern DMM's, even the cheap ones, come with a temperature probe..

73 de VK3BFA Andrew.

Hi Andrew,

This 830 is super clean in side and out. Fan has been oiled. We take care of our equipment on a regular basis. Nothing obstructing ventilation. Just looking for ideas to improve the cooling efficiency of the final compartment during more demanding modes. As far as temperture I have no way to check but to the touch it will approach the area of hot but still can leave your hand on the fan cover. Thank you Andrew for the suggestions.

73,
Art

Art,

"ideas to improve the cooling efficiency of the final compartment during more demanding modes."

PSK, RTTY, and SSTV (MSSTV or EASYPAL) are typical digital modes used on the ham bands today. Each of these modes operates at "100% duty cycle" which produces RF output 100% of the time the transmitter is sending data or digital tones which produces more heat.

Keeping the power output low, transmission times short, and receive times longer will help reduce excessive heating in the finals. The final amplifier will still become warm when operating these modes. Adding additional fans or a bigger fan will not stop the final from heating, it will simply move more air.

Hi Mike,

Thanks for the interesting input. I understand that extra air will not keep the final from heating but I would think more cool air would keep the components cooler. I never really though of it the way you explained it. Interesting.

Here is an update. I can get about 80W on 80m CW. I have made several contacts with the rig on CW. I don't have a mic yet to test SSB. Overall, it is a very "lovable" rig.

It is strange that I get the most power out of the rig with the carrier knob turned down to zero. If I turn it up the carrier, the power quickly rolls off at a setting of one. I am hopping some of you long time aficionados might have seen this before.

Thanks,
Chris KQ6UP

20764. TS-820S DG-1 Mixer Board "glitch"

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-02 17:15:50 UTC
From: jsloss
Topic: 20764 Message: 20764

My digital readout developed an interesting "glitch" yesterday. I've isolated problem to the Mixer board by installing a known good Counter module and then a known good Mixer board - both which corrected the problem. Screws have been tightened, connector contacts cleaned, solder inspected to no avail. Freeze Mist does not restore the board to correct operation.

When tuning from 7120.0 to 7139.9 the readout is correct. At 7120 it jumps to 7160 and tracks correctly but is 20 Kc high.

It does this on any band and throughout the band in use. On several frequencies the "tens "" digit goes blank as fols:

7179.9 reads corrrectly, At 7180 (per analog dial) digital goes to 71_0.0 and tracks correctly to 71_9.4

At 7200.0, readout now reads 7220.0 (it should read 7200.0,) and around we go again!

Would appreciate input from those comfortable with digital stuff

No, no, no I have seen this on my TS-830. I had to re-read the manual and complete initial settings (such, as turning the mic gain to the "calibrate" position). For me this solved the same problem if this isn't your problem then I did not mean to bother you. Chris, W2ALQ

Place the meter switch in the RF position and the mode switch in either USB or LSB. Connect the radio to a dummy load. Turn the MIC gain completely counter clockwise, minimum MIC gain setting. If your dummy load has a watt meter then that will also work. The idea is to look for RF output WITHOUT modulating the radio in sideband mode.

Place the SEND switch "UP" and the 520 should key. Look at the RF meter. If the RF meter on the 520 or your dummy load watt meter indicates a reading then the carrier null adjustment needs to be done.

There are two kinds of Jones connectors and a alike.
Problem is that they have the numbers mirrored on the connector.
This has caused many a Yaesu owner much grief.
So if you finish a power cable, measure twice against the original schematic.

My 2 cents

Yea, that was a pain. I was going by the numbers on the Jones plug.
When I took the bottom cover off I noticed that they were a mirror of
what they were supposed to be. The rig is working now. I am trying to
sort out a couple of other issues with the rig now.

Thanks,

My Watt meter moves almost imperceptively. Does it need adjustment if it is a tiny, tiny amount? I am also hearing part of the lower passband when in CW mode (receive). I don't hear beats on both sides of the carrier when I am in USB or LSB (this is a good thing).

Hello Chris,

The CAR control varies a positive DC voltage that is applied to the balance modulator (balance modulator is located on the GENERATOR UNIT X52-1090-00) in TUNE and CW mode. The source for the 9VDC originates on the FIX CH AVR Unit (X42-1100-00).

The CAR control is active ONLY in TUNE and CW mode. The CAR control is NOT active in either USB or LSB.

To check and adjust the 9VDC and 3.3VDC, perform the following simple steps:

1. Measure the voltage on the FIX CH AVR Unit's "9" terminal. If necessary, adjust VR1 on the FIX CH AVR Unit for 9VDC +/- .1VDC.

2. Measure the voltage on the RF-1 terminal also on the FIX CH AVR Unit. If necessary, adjust VR3 on the FIX CH AVR Unit for 3.3VDC +/- .1VDC.

Adjust the 9VDC "FIRST" then adjust the 3.3VDC. The above adjustments are found in the TS-520S service manual on page 45 "RECEIVER SECTION" at paragraph "2" titled "SETTING THE 9 VOLT POWER SUPPLY and FET BIAS SUPPLY VOLTAGE". The 9VDC powers not only the VFO, both internal and, if used, external, plus a number of other circuits. The 9VDC flows through the FUNCTION switch AND pins 8 and 9 on the rear 9 pin external VFO socket. Clean the FUNCTION switch with contact cleaner (DeoXit) and ensure the connection at the rear 9 pin VFO socket are clean and secure. Clean the plugs that plug into the rear of the VFO.

The procedures for adjusting the carrier null are contained in the TS-520S service manual on page 50 under the section titled "BALANCE MODULATOR AND CARRIER ADJUSTMENT".

Clean the CAR control with contact cleaner, remove excess contact cleaner with canned air and test for proper operation of the CAR control, correct RF output, and check for carrier in sideband mode.

If you do not have the TS-520S operator and service manuals, you can download them free at the following website:

http://www.n6wk.com/kenwood/

Chris,

I actually can't say whether your wiring of the Jones plug causes the problems or not.

It does appear, however, based on your comments about hearing the CW beat note on both sides of the carrier at equal levels that the CARRIER UNIT may not be properly aligned. Other stages may also be contributing to your problem as well.

An improperly aligned CARRIER UNIT will affect both transmit and receive, including the drive level to the driver and ultimately the final amplifier's output signal level.

In transmit, for example, "IF" the CARRIER UNIT's frequencies are OFF FREQUENCY, the CARRIER UNIT's RF signal will NOT be placed at the proper crystal filter's passband "position" as I call it. If this occurs, the "normal" crystal filter output signal level will be affected (reduced). If the crystal filter's output signal level is reduced below it's normal level, the signal level fed to the driver tube and ultimately to the final amplifier will be "less", hence lower output from the final amplifier!

In receive, for example, "IF" the CARRIER UNIT's frequencies are OFF FREQUENCY, the problem you are experiencing, hearing both sides of the CW carrier beat note, can and will occur! Remember, the CARRIER UNIT provides the "BFO" siganal in receive and it must be on frequency for everything to work properly!

Does the SSB filter affect the transmit of the 820? In other words is the filter switched out on transmit and not used. If it is used to limit the bandwidth of the of the audio, is there a better filter than the YG 88s? I think this filter is 2.1k, and sounds funny to my ear. Was there a wider filter made such as a 2.8. Gene

Geme.

The filter(s) in the 820 are not "switched out" in transmit.

I recommend checking the Carrier Unit and VCO alignment before spending money on a filter that most likely will not fix your problem.

I found my 820's CAR1 and CAR2 alignment as well as the VCO alignment was off quite a bit. Once I performed the alignment of the CAR ASSY plus the VCO, I noticed a significant improvement in the 820, both in receive and transmit.

Hello,
Cleaning this ts-530s as best I can. I cannot remove the nicotine stains from the upper circuit boards. I've heard of people soaking circuit boards in soapy water to clean them. Is this true or a legend? If it is true could someone give me the details? I need to clean two boards that are quite sticky. Any other ideas appreciated too. Thanks & 73, Phil k2pjw

Hi Mike,
Thanks for the link! That picture says it all....I'm still afraid but I'm gonna try it! Boy I love these old Kenwood radios. Best 73, Phil k2pjw

Ok

Got the repair kit from K4EAA and replaced the requisite resistors…that fixed my IP issues now with just a bit over 200mA I get 125W out on 20m. One of the cathode resistors was 27 ohms and the other was 39.

But the issue with delayed output response is still there after the rig warms up. Sometimes not having any output at all or having swings in the output and then after flipping it to send it takes a couple of seconds to respond (in tune or CW).

Ken, K4EAA, suggests that it is RLY1 and yes…tapping on the relay will affect output. So I removed the AF board to determine how difficult it would be to remove the relay and I think someone at some point in time has futzed with my AF board. There are a couple of components on the bottom of the board (an electrolytic and resistor tied together – perhaps that was a service bulletin?) Plus another disc cap and resistor that I don't see on the schematic and it also looks like someone at some point replaced the audio output amp and didn't do a good job of it on the soldering.

So I think I'll just order an AF board from Bob Mansker and pop that in instead of messing around with the current board.

Tate,

I agree with Gordon, replace all 4 of the final tube cathode resistors, R2 thru R5, with new 20 ohm 1/2 watt resistors.

300ma plate current in the final tubes is way too high! Continued operating the 830 at this high current level will not only cause early tube failure but it can easily result in power supply failures which could lead to failures in other components/circuits as well.

At this point and based on your comments about the cathode resistors, I disagree with your idea the problem is the HV supply. Replace all 4 of the cathode resistors then check for

final amplifier stability. Only then if the problem continues would I agree to check the power supply or other areas for the source of the problem.

Tate,

The TS-830 service bulletins are available direct from Kenwood's website, free. Click on the following link, scroll down to the Amateur Radio Service Bulletins, click the drop down menu and scroll and click on TS-830S. The service bulletins will show up as links to download after you click on TS-830S.

The HC-5 is a 2k element, so low-ish impedance compared to the 50k that the TS-520S seems to expect. Still, I don't see any reason for it not to work. It's not low enough to have a serious effect on performance, although you may need to crank the mike gain a bit.

Some sort of preamp would be good, or a matching transformer.

Gordon

Washing boards is pretty common in the vintage computer world. Many vintage computer restorers use a dishwasher and a non-abrasive automatic dishwashing liquid. The choice of "soap" is important because most contain abrasives or large amounts of chlorine. Using a small amount of soap addresses the chlorine problem.

One thing I've always done when washing electronics is to flush the board with lots of isopropyl alcohol (rubbing alcohol, 90%). Isopropyl aggressively bonds with water and will draw it away from components and tight locations (under IC's for example). After you've chased the water away the isopropyl will easily evaporate with a little sunshine or warm air (hairdryer).

Sadly, labels and markings don't always survive such treatment. I wouldn't want to try it with any components made of wax or paper, like a radio from the 1950's. I've yet to see component markings suffer.

Gordon,

Thanks for your response, I have the Heil Gold Line that I purchased along with my TS-2000 3 1/2 years ago. And at that time I also purchased an extra HC-5 element that I have never used. So I though maybe put the element in a mic case and try it. The HC-5 sounds great on the TS-2000.

Thanks
Mike

You won't hurt anything by trying it. At worst, it won't sound very
good.

Is anyone using a Kenwood Hybrid for data?

I've just tried my TS-520se on BPSK31 and it's drifting enough to be a problem. When it switches back to RX after TX the frequency is slightly off on the waterfall. The sets been on for over an hour so it should be as stable as it's going to get by now. Does anyone else use their set on BPSK31 without any problems? Do I have to take the covers off again ? :-(

Sounds like yours might be a bit drifty. Mine's pretty stable and works well for PSK31.

Make sure you keep the TX power down. For licence reasons I run at 10W measured at the antenna (the legal limit for MM3 or indeed any M3 licence - cue the braying from the peanut gallery "got your licence off the back of a cornflakes packet" - actually it was off the back of Shreddies packet, shows what you know) which helps keep the PA valves nice and cool. You don't need a lot of power for PSK to work well - with several contacts into the states on 20m running full power made no difference to the received signal (and probably just made it splatter).

There is a fix that has been discussed on this list before, which sorts out the regulation for the VFO power. I've never done it, because my TS-520 is pretty solid once it's been on for a couple of hours. Keep the room at a steady temperature and keep a gentle hand on the throttle, and it should be okay. It's probably also worth reviewing the past few posts about keeping the fan and PA cage clean.

Hi Gordon,

I seem to have sorted this out. I'm using the line in, line out sockets into a laptop and I was turning the mic gain down to give around 50 watts RF out. I've just checked the Ip and found it way too high for 100% duty. I've now turned the gain down further to give Ip of just over 100mA and an RF out of around 30 watts. I'm now getting good reports and it's stable. A couple of thoughts though. Seems likely that the power supply is sagging after a heavy load so is there a power supply problem? an secondly the ALC needly isn't even on the scale so how is the VOX working ?

The sets nice and clean. I've only just got the covers back on after setting it all up.

I don't know if you use this http://psk.gladstonefamily.net/pskmap.html
It's good to see how your signals getting out. I'm just getting to the UK this afternoon so if you've got time look out for me on 20m.

..... and I wouldn't knock the M3's or even the MM3's ;-) . It's a good way to get people into the hobby.

That should work okay. I used a 6dB pad to knock the output of the TS-520 down a bit and plugged it into the mike in on my laptop.

> around 50 watts RF out. I've just checked the Ip and found it way too
> high for 100% duty. I've now turned the gain down further to give Ip

You could also look at the 9v biasing mod, where you apply a little negative bias to the ALC pin. This lets you turn up the mike gain and get the modulator driven properly, but turns down the power on the PA.

There's a mod you can do where you can switch in the resistor for the PA screen grids which is used in TUNE, and takes the PA down to half power.

My understanding is that the VOX comes off the mike input. For there to be any ALC at all the set would need to be in transmit, so that wouldn't be useful for VOX...

I haven't seen that, but it looks pretty useful.

I'll have a play with that just now, and fire up the rig.

> ..... and I wouldn't knock the M3's or even the MM3's ;-) . It's a

Some people seem to forget that they did a novice licence too. They're probably the same people who drive aggressively around learner drivers.

>the power supply is sagging after a heavy load so is there a power supply problem?

When current flows through a tube a voltage drop occurs in the plate circuit of the tube. This causes a reduction in the tube's plate voltage and is referred to as "voltage drop". As the current through the tube increases, so does the voltage drop in the tube's plate circuit. This is normal tube operation.

Age can take its toll on power supply filter capacitors. Age causes increase in the capacitors internal leakage current. As the capacitor's internal leakage current increases, internal capacitor heating also increases. An indication the capacitors need replacing is when a "dimple" or small "pimple" is seen on the positive side of axial lead capacitors or in the case of the HV filter caps in the hybrids, on the bottom. If the caps in your 520SE have this "dimple" or "pimple", some may even have a broken bottom seal, then it is time to replace the caps. Any "physical" leakage on the positive side or bottom, the capacitor should be replaced regardless of how good they may "appear" to be. Physical leakage is a sign the seal has been broken. The broken seal is caused by excessive pressure build up inside the capacitor due to excessive internal capacitor heating.

>an secondly the ALC needly isn't even on the scale so how is the VOX working ?

ALC has nothing to do with the VOX circuit nor does it control whether VOX works or not. VOX is an "audio" circuit.

ALC occurs ONLY in transmit, never in receive! ALC is a "transmitter" controlling voltage and has absolutely nothing to do with receiver's S meter or any receive function.

ALC is a "by product" of grid current in the final tubes. Grid current slows in the final tubes when the grids are driven "positive" and ONLY when the tubes are driven positive. When grid current flows in the final tubes, the ALC circuit "senses" the grid current. The ALC circuit "rectifies" the grid current into a DC voltage that varies at the same rate as the grid current. This "DC voltage" is now the "ALC" voltage that is fed back to an earlier stage to control the gain of the transmitter just as AGC does in a receiver.

ALC has not control over the speech amplifier nor will it reduce distortion in the speech amplifier's output!

One last thing. A better method of connecting a sound card interface to the 520SE is to use the rear panel's Phone Patch In and Phone Patch Out sockets. If you are using VOX to control the keying of your 520SE then VOX is still available when using the Phone Patch In socket. The MIC gain still controls the audio levels in the 520SE just as though the sound card interface was connected to the MIC socket. The front panel volume control controls the level of audio output level at the Phone Patch Out socket.

Hi James,
Thanks for the information. Could you recommend a "soap" that you use? If possible could you recommend a "lube" to use for the movable parts? I have different kinds here, however, I have mostly mechanical lubes that wouldn't work well in an electronics environment, IMHO anyway. Thanks!

Topic: 20790 Message: 20796

Drift in the TS-520SE is primarily due to drift in the 9VDC source. The 9VDC is produced in the FIX CH AVR UNIT from the 14VDC supply.

The VFO is powered by the 9VDC supply and if the 9VDC supply drifts, it usually drifts upwards, the VFO will drift which leads to drift in the 520SE.

If the drift is excessive then the current regulator transistor Q4 (2SA606L) on the FIX CH AVR UNIT and zener diode D3 (WZ-061) also on the FIX CH AVR UNIT should be replaced.

To adjust the 9VDC and 3.3VDC, follow the steps listed below. These steps were obtained from the TS-520SE service manual.

Remove the top cover of the 520SE. The FIX CH AVR UNIT board is directly behind the VFO.

Locate the pin labeled "9". Connect the volt meter's positive lead to this pin and the negative lead to chassis ground. Adjust VR1 on the FIX CH AVR UNIT board so the meter indicates 9VDC +/- .1VDC.

Move the positive meter lead to terminal "RF1". Adjust VR3 so the meter reads 3.3VDC +/- .1VDC.

That's it.

20797. Wafer alignment

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-05 02:00:56 UTC
From: k2pjw
Topic: 20797 Message: 20797

Hi,
I made a rookie mistake. When I removed the RF board from my ts-530s I left the bandswitch in the 10Mhz position. That's all fine except the wafers on the RF board are all outta whack from my cleaning, checking, etc. Is there a trick to knowing how to get them all in their proper orientation again? Thanks.

20798. 520 Alignment again

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-04 22:35:07 UTC
From: Jim Fish
Topic: 20798 Message: 20798

OK, I've run out of ideas now. I still cannot get this 520 to align on 20, 15, or 10 meters.
While the first two 10 meter crystals have been changed out to work on CB, I still want
to at least get it working on 15 and 20 before springing for new crystals.

So yesterday I really got into it. I removed the Antenna coil unit as well as the Mixer
coil unit. I re-glued loose coils back in place and made sure they had all of their
winding right, wound the same way, and cleaned off some old rubber like glue that has been used previoulsy in a poor attempt to repair loose coils. I made sure
that none of the capacitors had been changed. I made sure that the switch contacts were clean and working. I even put my L/C meter across the 40 thru 10 meter coils which are in series and watched the value change as I rotated the
switch thru its band positions. I made sure I could see changes in values when
I turned the slugs in and out. On 10 meters only one coil caused a change. On 15
meters, two coils could cause a change. On 20 meters, three coils could cause a
change and on 40, all four could cause a change. Just what I expected to see.
The same happened on both boards. I put it all back together and I have the same problem. Nothing peaks on 20, 15, or 10.

The hetrodyne crystals are all working great. I can hear them on my station receiver and I can see them on the scope. They are all adjusted to 1 turn after they start to oscillate per the manual. I see no changes under the RF board and near as I can tell, the only mods were the crystal changes.

So what am I over looking? It must be something simple but I've run out of things to look for and tests to make.

73's from a stumped Jim, K7NCG....

20799. Re: [TS-520_820_530_830] Wafer alignment

Hi Phillip,

There's some info on switch repair here - http://www.k4eaa.com/bandswitch.html

The most important paragraph is included below

Now the switch wafers have to be removed, so you can measure and
repair them. This is best done one wafer at a time, so you don't get
them out of order. Use a good solder sucker to remove the solder at
each pin, and they will simply fall out. NOTE AT THIS TIME WHAT
GENERAL DIRECTION THE SWITCH CONTACT IS POINTING! You want to
restore it to this approximate position when you are re-assembling,
so all wafers will be "in sync" when completed. There is a notch in
the plastic on the rotary portion of the switch, if you observe this
and re-assemble them all the same with regards to the notch, it will
serve the same purpose.

It talks about a notch on the rotary portion of the switch. I suggest
you buzz the board out with an ohm meter once you have the switch
re-assembled to make sure everything is in order.

Good luck

Lou

Not a Kenwood, but years ago I built a Heath Kit single side band receiver from a kit. That radio had stacks of wafer switches to change bands (Kind of like a Kenwood) The switches would get noisy after some time and I would spray them with contact cleaner from Radio Shack. The stuff stank and was a mess to use.

One day I took the chassis out and sprayed all the switches and set it out on our patio to dry and air out.
Apparently our dog also found the odor pretty bad, so he pulled the chassis off the patio and buried it in the back yard.

I called Benton Harbor and asked if I could save the radio and I could hear the laughter all the way to California. The tech was telling everyone "I have some guy here and his dog buried his radio". More laughs and finally he gave me the same advice. "Dig it up, hose it off and rinse well with distilled water and let dry for several days and it should be OK." Worked well so washing a radio is good practice when needed. But be sure to allow ample drying out time before applying power.

There's a lot of choices in automatic dishwashing soaps. Avoid the ones that list anything that sounds like sand (silica-blah). Then take a drop and spread it out on your wet hands, wait a 1/2 minute and then sniff. If you smell chlorine (bleach) then skip that brand.

Generally, the one that does the trick is a "natural" or "save the planet" type brand.

If you don't have luck, don't use soap in the machine. Hot water and pressure do more work than you might think. Don't use hand dishwashing soap as it suds and the machine can't handle suds. I did have luck using tiny bit of an "HE" type low sudsing laundry detergent, but use the scent-less type or you'll have a flowery smelling dish load for a few loads after.

When I use soap, I always run the electronics through a full cycle without soap to assure good rinsing.

> At this point and based on your comments about the cathode resistors, I disagree with your idea the problem is the HV supply. Replace all 4 of the cathode resistors then check for final amplifier stability. Only then if the problem continues would I agree to check the power supply or other areas for the source of the problem.

Topic: 20806 Message: 20806

TS-520S - NUE-PSK group:

I have an old TS-520S and have been using it with my NUE-PSK modem for months with absolutely NO problems. I do have a DG-5 to track frequency accurately. Audio in / Audio out simple patch cables -- works fine lasts long time..

I reported this to the NUE-PSK group and George N2APB months ago.

Tate,

Check the voltage on the final amplifier's "SG" pin connection. If the "SG" voltage is unstable check resistors R15 and R16, both 56K, on the Rectifier Unit. You also might check RL1 on the Rectifier Unit. It is possible the contacts are dirty.

20808. ESD with the Hybrids

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-05 21:53:30 UTC
From: k2pjw
Topic: 20808 Message: 20808

Hi,
Before I start replacing questionable parts I thought I would ask if ESD is a big deal with these old rigs. When working on laptops, cpu's, etc.,I wear a wrist strap and use a rubber mat, etc. so I hopefully won't short anything with static discharge. Digging into my ts-530s it appears I need to be careful but maybe not quite so extreme as wearing the wrist strap,etc. What do you all recommend? Is this an issue with the hybrids? Thank You.

20809. Re: ESD with the Hybrids

Although ESD may not be as much of an issue with the hybrids as it is with computer boards, ESD is an issue with sensitive boards. I've never had a problem with ESD but then again, I try to place myself and the board at the same potential. If you have the ESD equipment then use it.

One of the great things about PSK is that because you're tracking two closely-spaced frequencies *somewhere* in the audio spectrum, you don't need to care too much about the actual VFO frequency just as long as you can find out your TX frequency.

That said, I check my TS-520 with the frequency counter once a week when I'm doing the rest of the provocative maintenance, just to make sure the calibrator is still singing the right song. It always is ;-)

Paul....

In YahooGroups, you can get messages 3 ways, and ONLY 3 ways,.

1. via email,
2. By Digest,
3, read on-line at TS-520_820_530_830@yahoogroups.com.

Messages cannot be filtered according to topic.

20814. Shure 444D and TS-520S

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-06 02:53:05 UTC
From: Christopher Maness
Topic: 20814 Message: 20814

I just recently purchased an ol' 520s and had a 444d in the junk box. I believe it is the stock wire. The Red and GND is the mic??

I see that the black and white is the PTT.

When I hook it up as such, I get very tiny deflection of my power meeter with the mic gain all the way up and the processor on. I am currently able to get close to 100W out on CW, so I don't necessarily think that it is tube issue.

Did I wire the mic correctly? I have learned through my experience as a sound tec that I still get a tiny amount of sound with one mic lead connected due to stray capacitance (in a balanced mic).

From: Tate Antrim
Topic: 20584 Message: 20815

Ah hah!!!!

SG voltage is perfect at all times (including TUNE).

Very tricky. Turns out it seems to be the big audio IC on the AF board. Letting the rig run for a couple of hours it will start to exhibit the problem of delayed response on output finally dropping down to nothing. My gut told me that something on that board is causing a problem. I ruled out the PLL and such because it was displaying the correct frequency and problem is on all bands and the display is rock solid. But what I noticed is that plate current drops to 60mA in CW when you hit send.bingo.acts just like USB/LSB when you hit Send and there's no audio to excite it.

I put my finger on the aluminum around the AF board and it seemed inordinately "warm" for just sitting there running. Flipping the switch to send would seem to increase the overall temperature. So I got out a can of canned air and blasted components around the area where it seemed a bit warm and all of a sudden output jumped up to 100w instantly. Letting off the cold air and output drops back to 0W.cold air on 100w out. Cold air off.0W. Wax on, wax off. So I narrowed it down to the big IC.

I noticed the other day when I have the AF board out that it looked like either someone at some point replaced the chip or tried to resolder it - either way it didn't look right. But it just didn't make the connection in my head.

So I think for now I'll try to get another AF board and I should be back in biz with the old girl.

Thanks for everyone's help.

Hi Joe,

I also wondered why Martin would recommend against getting posts sent
to an ISP email address. However, consider if I changed my ISP quite
often. I subscribe to a number of different groups, some through
Yahoo some not. It would be a real pain to change all those
subscriptions to my new ISP email address. Now if I subscribed to all
the groups using a gmail/yahoo/msn/hotmail/whatever account it
wouldn't matter how many times I changed ISP my subscription email
would always go to the right place - no hassles.

Perhaps that's what Martin was trying to say?

In any event that probably wouldn't help Paul. Seems he's having
problems with his user profile setup and as you suggested he needs to
select the "web only" option in the "Edit Membership" link. I've had
problems with this in the past because I have more than one user
profile. Sometimes they interact and don't behave the way you hope they would.

Regards

Lou

I was on the Internet and I found this... </clarkson>

http://www.qsl.net/yv5grb/shure444dmanual.htm

This seems to suggest that there's an impedance switch on the bottom,
which should be set to "high". It's always possible that the mike is
set to high impedance and the transformer is knackered, in which case
you'll want a preamp.

One of the reasons Heil designed this element was for use on Kenwood 520 and 820 radios. It was often used in place of the element in the MC-50. It should work just fine with the 520.

Hi Joe. My reason for suggesting that Paul not have the group mail
sent to his ISP email account is that he seems to not want to get/read
all the messages, only those on topics that interest him. The only
way to do that is to juat read the archives online. I suppose he
could just read the messages that he is interested in, and delete the
rest.

I have the group mail sent to my ISP email account, and have a folder
set up, and a filter so that this groups messages go to that folder.
Same with the other email groups I subscribe to. I do think that
using web mail as one's primary email account is silly, but to each
his/her own!

Check your line voltage first !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

The set can be wired for either 220 or 240 volts AC.

If you apply 240 volts to a set wired for 220, you have about 10 % more
voltage than requested.

It could be why your HV reads 970 volts in lieu of 900.

If you make any change, check the 9 volt regulated supply adjustment.

Just an idea...

Good luck & 73's - Daniel, ON5PY

BTW the UK line voltage is 230 V not 240.
The line level was dropped a few years ago

That's a nominal 230 volts, though. They changed the tolerance at the same time. Previously it was 240V +/- 6%, but now it's 230V -6%, +10%. Do you see what they did there? Kept the upper tolerance voltage almost the same (253V instead of 254.4V), thus allowing power companies to keep supplying 240V.

A quick check of the various systems tells me that my mains voltage has been bob on 240V for the past 24 hours here in Glasgow, and wobbling slightly between 238V and 242V at my site on Skye.

Well now, far be it from me to suggest such a thing... ;-)

No doubt it's written up as one of these "for your convenience..."
things.

Hello Tate,

With the additional information you provided especially giving Q4 on the AF UNIT a shot of cold air, it appears you have found the culprit that is causing your problem. The question I had was how does Q4 affect the transmitter output signal? This information may have been presented earlier but I may have just missed it.

Here is what I think is happening to cause the RF output to drop to zero.

When Q4 on the AF UNIT goes bananas it drags down the 12VDC supply. When this happens, Q29 on the IF UNIT is affected, basically shutting down Q29. Q29 on the IF UNIT is the "TIF" (Transmit IF) amplifier. The TIF signal is fed from the IF UNIT to the RF UNIT where it is mixed in Q6 and Q7 with the VCO signal to produce the "operating" frequency. If the TIF signal is missing in the RF UNIT then there will be no operating frequency to feed to the driver and final tubes, hence, zero RF output! By giving Q4 on the AF UNIT a shot of cold air, Q4 starts operating properly which brings the 12VDC source back to its normal level and Q29 operates normally and amplifies the TIF signal, the TIF and VCO signals mix in Q6 and Q7 producing the operating frequency and output is seen at the final amplifier.

I suspect if you placed a scope on the RF UNIT's "TIF" connection and when Q4 on the AF UNIT goes bananas, the level of TIF signal would drop considerably which would cause the RF output to also drop. Giving Q4 a shot of cold air will cause the TIF signal to return and will show up on the scope and output will return from the final amplifier. A VTVM connected to the IF UNIT "12" pin will also show a reduction in the 12VDC supply when Q4 goes bananas but will return to its normal level when Q4 s given a shot of cold air. Just a few thoughts I had.

Good job Tate!!

Hello,

Sorry, I didn't follow the whole case, but wouldn't it be possible to glue a larger aluminium radiator on Q4 ?? I remember a problem with a TV processor chip that drifted when heating. I removed it cutting its pins - 40 or 42... - to replace using a socket, but almost shot the new one because of a broken ground connection. Epoxying a radiator would have been much easier. Just my two eurocents....

It is definitely in the Hi Z position. I got an almost imperceptible deflection in the Low Z setting. I am not sure if I wired the mic correctly. I just met a new ham around he corner, and he said that he had an 830, so maybe I will see if I can test my mic on his rig.

Chris,

I am at work now and don't have access to my " laptop library". When I get home tonight I will send you a detailed wiring diagram for that mic and rig. I'll also include additional information regarding a simple wiring mod to the mic for VOX use that eliminates the need to lock the PTT bar and flip the switch on the bottom of the mic. The mod also gives you PTT over ride when in VOX mode, something the original wiring did not allow.

Hello Daniel,

That would be a possible solution if the chip did not have a heat sink already.

Based on Tate's comments, it appears a previous owner tried to replace the chip and did a bad job of it. Whether it's possible to "clean" up the mess the previous owner made, at least for my point of view, is not known. I would suspect Tate has thought of that and possibly tried cleaning up the mess. However, if Tate has tried that and no change was seen, then it does appear the audio IC chip is dragging down the 12VDC supply which is affecting not only the IF UNIT's Q29 but also other circuits in transmit plus I also suspect receive circuits as well. Of course Tate can answer whether he attempted cleaning up the mess from a previous owner.

Hey everyone.

I'm going to get a replacement AF board and pop that in for now. I agree with the comment that this is pulling the signal lines downstream way down. It acts like switching it to usb and no drive signal.that's what got me to thinking that there was something in the signal path that was sensitive to heat but really wasn't a relay issue. Once the cathode resistors were replaced and I had concrete proof that the IP was now "correct" and the suggestion to look at SG voltage yielded a very solid level between RX and TX (not to mention a couple of local hams offering suggestions on 160m last night). I fired it up and said to myself that I'm not going to let this girl go wither on a shelf but figure out what this problem is.

When I was an avionics bench tech (many years ago) we had freezie stuff in a can and I remembered how helpful that was in determining where things were having issues that canned air came to mind.giving a blast of that can frost the circuitry. One blast and it popped right up but instantly went down.

So now I've got a new board on the way and I'll get that component and replace it on my old board then store that one away as a spare. In the meantime I just want to get my favorite girl back on the air!!!!

But really, thanks to everyone for their suggestions. Now to get a sweep signal generator and a spectrum analyzer and maybe I can start a new career.well.anyways.

Subject: [TS-520_820_530_830] Re: TS830S - Strange Behavior - It's Back!

Hello Daniel,

That would be a possible solution if the chip did not have a heat sink already.

Based on Tate's comments, it appears a previous owner tried to replace the chip and did a bad job of it. Whether it's possible to "clean" up the mess the previous owner made, at least for my point of view, is not known. I would suspect Tate has thought of that and possibly tried cleaning up the mess. However, if Tate has tried that and no change was seen, then it does appear the audio IC chip is dragging down the 12VDC supply which is affecting not only the IF UNIT's Q29 but also other circuits in transmit plus I also suspect receive circuits as well. Of course Tate can answer whether he attempted cleaning up the mess from a previous owner.

> The procedures for adjusting the carrier null are contained in the TS-520S service manual on page 50 under the section titled "BALANCE MODULATOR AND CARRIER ADJUSTMENT".
Thanks for your replies. I noticed there is a similar (but simpler) procedure in the owner's manual (Pg. 39 6.8). The only test equipment I own is a DVM, and Oscilloscope. There are probably fellows in my ham club that have more test equipment if the procedure detailed in the service manual is more desirable.

How should I proceed?

I have just uploaded a photo of my 599D twins and also some photos of
a fan mod for the T-599D. The stock fan moves precious little air over the 6146's. The top of the cabinet gets very warm even when not making RF.
I machined a 1/8" thick aluminum manifold that covers the existing fan opening and allows for an 80mm 110VAC computer style fan to be attached to the manifold. The new manifold is attached to the 599D rear apron with stainless metric flat head screws- using the existing tapped holes (4) from the old fan enclosure. The new 80mm fan then attaches to the manifold with (4) stainless 4-40 X 5/16" socket head cap screws and flatwashers into the tapped holes of the manifold. The original Kenwood plug is removed from the old fan and soldered to the new fan. Now, the top cover stays at ambient room temp - absolutely no detectable heat build up. The new fan is oriented to exhaust air from the P.A. compartment. All the original parts are boxed and saved. No new holes or permanent changes are required to the T-599D

Dale,

Has there been an increase in fan noise? Those little fans create a
lot of noise compared to the Kenwood fans I've heard.

Hi Lou,
I used a ball bearing fan and I can hear the fan noise if the RX volume is off or Standby- but with any RX audio at all, it masks the fan noise entirely. Just a bit louder than the stock fan.

Hello Chris,

The carrier null procedure in either manual accomplishes the same thing. The service manual states to use a VTVM with an RF Probe connected to the 520's antenna connector (center pin of the rear SO-239) where the operator's manual uses the 520's RF meter position. Either method will work. However, a more accurate method is to use a separate receiver tuned to the same frequency and sideband(s) the 520 is.

When using a separate receiver, DO NOT connect the separate receiver to the 520!! Doing so can damage the separate receiver.

First, tune the 520 into a dummy load for maximum output as outlined in the manual's operating section. Then tune the separate receiver to the same frequency and mode as the 520. Place the 520 in USB, or LSB, as stated in the manual, set the MIC gain completely counter clockwise (minimum MIC gain setting), key the 520 into a dummy load with the SEND switch and adjust TC1 and VR2 on the 520's GENERATOR UNIT for the lowest S meter reading on the separate receiver. Switch sidebands and perform the adjustments again. As stated in the manuals, you will have to alternate between sidebands and adjust TC1 and VR2 a number of times to obtain the best carrier null.

I use the separate receiver method on all sideband transmitter carrier null adjustments I make. Whether you use the manuals methods or a separate receiver method is up to you. The key is to adjust VR2 and TC1 on the GENERATOR UNIT in the 520 for the lowest carrier output in USB and LSB.

Topic: 20840 Message: 20840

While tuning the TS-520, the following conditions were observed:

a) At the IP position and the mode switch is in LSB the meter reading is approx at 60 ma.

b) At the ALC position and the mode Switch is in the tune position the meter would peak when the send switch is energized but would immediately go to zero. No response on the meter when Drive knob is turned.

c) At the RF position and mode is at CW, when the Send switch is energized the meter would slowly decrease in value after peaking on both the Load and Plate knobs.

I have shut down the rig.

Pls advise what these conditions are telling me.

Hello Jojo,

From your description it appears the driver tube may be failing.

The 60ma IP meter reading is the transmitter's no RF drive signal idling current in the final tubes. This is the correct idling current required for the 520's Class AB1 final amplifier setting. If the 60ma idling current holds steady then it's quite possible the final tubes are OK. Therefore, I recommend replacing the driver tube (12BY7) first.

You are welcome Jojo. While it's possible that excessive key down time spent tuning the radio may have affected the tubes to some degree, age also plays a roll in vacuum tube life span.

hello again,,
a friend of mine just acquired a new to him ts-520s
during check out/tune up he discovered that the ip wont get 60 mills
in an effort to give him help,,where should we start looking?
recieve seems ok but when trying to tune up,,he gets stopped at step one by the not being able to get 60 mills,,any help??
did try adjusting the bias and no dice,,

One sure way to tell which wires are the PTT put your ohm meter on two wires and press the PTT button. Ground (shield) is one of them depending on how the mic was wired. Your meter will show continuity when the button is pressed and open when its not. That leaves you with the other two wires that have tobe the mic itself.

I was on the Internet and I found this... </clarkson>

http://www.qsl. net/yv5grb/ shure444dmanual. htm

This seems to suggest that there's an impedance switch on the bottom,

which should be set to "high". It's always possible that the mike is

set to high impedance and the transformer is knackered, in which case

you'll want a preamp.

While tuning the TS-520, the following conditions were observed:

a) At the IP position and the mode switch is in LSB the meter reading is approx at 60 ma.

b) At the ALC position and the mode Switch is in the tune position the meter would peak when the send switch is energized but would immediately go to zero. No response on the meter when Drive knob is turned.

c) At the RF position and mode is at CW, when the Send switch is energized the meter would slowly decrease in value after peaking on both the Load and Plate knobs.

I have shut down the rig.

Pls advise what these conditions are telling me.

What is the 520's HV meter showing?

The 520 must be keyed to display the HV.

Set the meter switch to HV, set the MODE switch to USB or LSB, flip the SEND switch up and read the HV on the red x100 scale.

Once read, flip the SEND switch down to unkey the 520.

Typical HV meter readings are 850VDC with the transmitter keyed but no output, just final idling current (60ma).

Hello Larry,

Have you perform the final amplifier's bias setting as discussed on page 21 of the 520's operator's manual first? If not then I recommend performing that step "first" before attempting to tune up the 520.

I assumed you had performer that step since you were at the tune up stage but I may have thought wrong.

20856. R-599D AGC Overshoot

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-07 22:34:29 UTC
From: Dale Parfitt
Topic: 20856 Message: 20856

Has anyone here had experience with this? I have noticed that a strong CW or SSB station will almost mute the RX when they first start talking (or at the beginning of a character). Although I have yet to put my scope on the AGC line- it certainly appears that it is overshooting on attack.
Any comments before I dig in?

Tnx,

Dale W4OP

20857. TS-830s transmit switch left on.... ?

I have had a similar experience and found that it was a dirty AGC time constant potentiometer. After cleaning the poteniometers in the AGC circuit and setting things "by ear"....it worked OK. The Kenwood service manual did not address the AGC set up, or alignment. Does anyone have that info???

Without the heater switch in the "on" position the output valves cant draw current so you wont have caused any damage.

There should not have been any tx with the heater switch off, so no harm to the rig that i can think of.

Hello....Have TS-830s set up to receive only, with long wire plugged into antenna connector (still setting up my shack).
While setting up to listen to the 3.925 net...noticed the transmit switch was set to transmit, instead of receive.
Switch was in transmit position for approximately 5 minutes....

Heater switch was off / Mic & Car were turned fully down.
Did I damage anything?

thanks....!

Hello again Jojo,
Hardly any difference in characteristics between 12by7 and 12by7a. But I think the driver in the TS520 is a 12by7a. I have a TS530 but I believe the output stages are a similar design and the fault you describe is indicative of poor emission from the 12by7a. You can get these quite cheap on Ebay.

Date: Tuesday, 7 April, 2009, 12:17 PM

While tuning the TS-520, the following conditions were observed:

a) At the IP position and the mode switch is in LSB the meter reading is approx at 60 ma.

b) At the ALC position and the mode Switch is in the tune position the meter would peak when the send switch is energized but would immediately go to zero. No response on the meter when Drive knob is turned.

c) At the RF position and mode is at CW, when the Send switch is energized the meter would slowly decrease in value after peaking on both the Load and Plate knobs.

I have shut down the rig.

Pls advise what these conditions are telling me.

73,

jojo

Afternoon Larry,

Since the bias control does nothing to improve the idling current then I recommend checking the following voltages at the final amplifier tube sockets

1. Screen pin 3 - 258VDC in receive - 231VDC in transmit

2. Grid pin 5 - minus 93VDC receive - minus 52VDC transmit

3. Plate cap - 958VDC receive - 858VDC transmit

It is possible the final tubes are very weak. If you have a spare set, use them. If the final tubes are Japanese S2001s then 6146Bs can be used as replacements.

I also recommend checking each resistor on the HV Unit. The HV Unit is the small PC board on the bottom and just forward of the power transformer.

The voltages in the above steps originate on the Rectifier Unit, the PC board on the bottom and to the left of the power transformer.

Replace any/all components that show signs of overheating/burnt/crack or otherwise physical damage.

Place the 520 upside down with the front panel facing you.

Always use caution when measuring high voltage! NEVER ASSUME the voltage has bleed to zero!! CHECK IT with a volt meter!! Take your time.

Since you didn't specify your repair/technical skills, I'll assume your skills are limited.

If necessary, turn power off to the 520, unplug power cable from wall outlet, discharge filter capacitor to ground using an insulated (NO WOODEN HANDLED!!) handled screw driver or shorting bar, connect volt meter, check for shorts from volt meter positive lead to ground, plug the 520 into the wall outlet then apply power to the 520. Do the reverse when disconnecting the meter leads.

Mike,

I have a question about replacing the Driver Tube (12by7a) in the 520S, The shield that covers this tube in this radio has a ground strap connected to it from the base that's on the RF board. Do I have to take the "Load" shaft out and lay the shield and tube assembly down to replace it or is there an easier way.

Thanks
ki0gv

On mine, the earth strap is just kind of "sprung" against the shield.
The valve comes out with its shield around it, which you can then slide
off and push the new valve in.

Maybe it's supposed to be more firmly attached, and someone's "had a go"
at mine in the past?

Hi Michael and Gordon,

On my TS830M there is a thin metal strip which is attached to the valve base.
This metal strip is roughly 2" long and is placed between the valve and the shield.
The valve is installed with the metal strip running up the side of the valve glass,
the metal shield is the slipped over the valve, keeping the metal strip in between the
valve and the metal shield.This is how the metal strip makes contact with the shield.

Marc.

There is nothing magical or secretive about the "rod" connected to the center of the driver tube socket.

The "rod" provides a ground for the tube shield when the shield is slide over the tube and the rod.

If the rod is missing/broken, sliding the shield over the driver tube has a significantly less shielding effect than if the rod were present.

Shielding tubes has 2 affects:

1. Prevents radiation of signals from the tube itself to surrounding circuits.

2. Prevents tubes from "picking up" signals from surrounding circuits.

I have not experienced any adverse affects during operation, both transmit and receive, with or without the shield over the driver tube. You can make your own decision whether to use the shield if the rod's broken or not.

Is anyone running the 6293 pulse tube in place of 6146A's in their Kenwoods? If so, any issues like difficulty neutralizing?
These tubes appear to be readily available at a competitive price to the 6146 but are said to be much more tolerant of high short term Ip.

Finally, what Po are you guys seeing on the T-599/TS-520 etc from a pair of 6146?

Tnx,

Dale W4OP

I`ve been licensed since 1988 and have been sitting on my new TS-520 since 1989. I never been in a position to set up my radio, untill now.
I just got me a house with a backyard, although it`s very a very small lot. I hold an Extra Class ticket but I virtually have no experience.
Since I couldn`t get on the air, all I did was study (self taught). Right now I feel like I know nothing. I`m not very tech savy either. I`m a bit overwhelmed in trying to get things set up.
Since my backyard is really small and I`m mostly interested in 80 & 40 meters, I determined that I will set up a verticle antenna.
I don`t know what I`m going to do when it comes to grounding? How does someone with a tiny car get a eight foot ground rod home? Lightning protection, transmission line, etc etc. I guess I have allot of stuff to order and get straitened out before I set up my antenna (which ever that one will end up being). I got moles in the backyard also so I guess I`ll have to run the coax inside of a buried pvc tube. Grrr. To my understanding, moles will chew on the coax cable? I sure could use an elmer right now. The local radio club seems to be a bit unfriendly. About three years ago I went to their Field Day and I was invisible.
Anyhow, I soon will be on the air with the rig. Hopefully it still works? LoL. 73`s Kyle N0MKH

Welcome Kyle!!

Well grounding isn't as tough as you think and in a pinch you can get up and running with out a ground. Be warned you can run into RFI issues with no ground but you can get up and running.

A grounding rod closest to the transmitter is always best, sometime not practical. I typically make an access plate with SO-239's mounted in it where the coax comes into the house. Then I use a brass bolt to run from the mounting plate to another ground rod. This gives a grounding point on all my transmission line right before it comes into the house. Now if you are dealing with a single coax run. Look for a Andrews 1/2" grounding strap. You can just use a threaded SO-239 and make a tab to attach a grounding lead.

I think the "Lightning Arrestors" are over priced junk.

Just because you are on a small lot does not mean you are limited to a ground mounted pole vertical. Inverted L work well and cheap to build, full wave loops are great. I run a 160M loop for about every band with a SGC-239 tuner and it blows my hyGain AV-620 out of the water on every band. Might think about one of those tuners and a $35 500" spool of 14AWG wire at lowes and start playing around. Put up as much wire as you can get up and forget about it.

Make sure you have a fairly accurate SWR meter, calculator, dummy load, and antenna tuner. Start experimenting... its fun :) Those SGC tuners are handy because you can about tune up a coat hanger on any band in a split second.

Anyways got any questions just ask... probably the nicest group of hams on the internet reside right here.

Regards,
Aaron

Hi Kyle
If you want to run some coax underground try using a length of 1/2"
hardline, something like Andrew LDF4-50, that has a solid corrugated
copper outer. There's always plenty of it around on the surplus market.

The other thing you can do is lay some plastic pipe and feed the cable
up that. When you want to run more cable out you feed it through by
tying it to to the draw cable you left in there, joining another length
of draw cable on in a loop. You *did* remember to leave the draw cable
in, right?

Kyle Welcome, hope you enjoy the group here and the hobby, and purchase of
the home.
Ground rods will fit even a small auto, just roll down the back window,
place the ground rod inside something or wrap it and extend it
through either over the front seat or if you have two seats/console, let it
go through to the front floor board. You just need something
around the ground rod where it comes in contact with the back window.

Since you are on a small lot, you could also use a dipole. One that I have
used in the past and I was introduced to by a good
friend (WD8PNL) is to use Radio Shack Speaker Wire. Get the type that has
the clear insulation, and split the wire down the
middle to the approriate length for the band(s) that you wish to cover.
Then you place electrical tape or a mechanical
device to stop the duples wire from splitting any futher, and you use the
remainder of the speaker cable as twin lead
feeder between the shack and the antenna. *You will need to use a balanced
tuner* with this and then coax
from the tuner to the rig. You should be able to pick up a tuner for a
small sum on ebay, but make sure it will handle
balanced line.

Also, I would suggest you have only a Single Point Ground. Do NOT run
multiple ground rods unless they are all connected
with at least #6AWG wire - you do not need different ground potential
problems either. There is a pretty good chance that you
already have the ground rod installed outside of the house from where your
main Breaker panel is now located. Do not
know how far from the shack that is located however.

Hope some of this helps, if you like you can contact me off list.
You will be really nervous when you make your first contact, but DO IT,
after that they all get easier..

Good Luck, 73

20886. 60 meter bands on 520?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-10 06:39:23 UTC
From: gr8raoul
Topic: 20886 Message: 20886

Has anyone tried to tune up on 60 meters yet?

Since 60 in the USA is a channelized band, putting some crystals in the mainly unused 'fixed' crystal slots might work if the adjustable circuits would resonate enough for 60. 60 meter crystals would probably have to be custom ordered but it would put my 520 on another band.

On a similar note, has anyone ever used 'fixed' crystals on any band and, if so, were the crystals available off the shelf?

Jeff,

Unfortunately this will not work. Remember, the FIX CH function "replaces the VFO" and provides one of the following:

1. Crystal control transmit, VFO receive

2. VFO receive, crystal control transmit

3. Crystal control transmit and receive

nothing more.

Therefore, simply plugging a 60 meter crystal into one of the FIX CH sockets will not place the hybrid on 60 meters. It will take more than a crystal, a lot more, to put a hybrid on 60 meters. For example, the VFO frequency range would have to be changed which would affect the entire mixing process. The hybrid VFO's operate between 5.000mhz and 5.500mhz (FIX CH crystal, when used, replace the VFO as I stated above) which is above and below the 60 meter band. Simply changing one of the heterodyne oscillator crystals will not do it either. Conflicts with the VFO will occur.

Topic: 20584 Message: 20888

Good news.I got a replacement AF board hooked it up and have a fully functioning 830S. The component that went bad is the HA1368R audio amp. Cooling it with compressed air would bring the rig up to full power instantly. Letting it warm back up and the power would drop off instantly.

As it is now, I'm trying to find a new one (well a NOS one) and redo my board so that I have a spare.

Incidentally, the replacement board had some work done on it as well to replace the relay in corner and comparing it to mine noticed that it was not in a "clean" an environment. But at least I have my 830S working again.

Subject: RE: [TS-520_820_530_830] Re: TS830S - Strange Behavior - It's Back!

Hey everyone.

I'm going to get a replacement AF board and pop that in for now. I agree with the comment that this is pulling the signal lines downstream way down. It acts like switching it to usb and no drive signal.that's what got me to thinking that there was something in the signal path that was sensitive to heat but really wasn't a relay issue. Once the cathode resistors were replaced and I had concrete proof that the IP was now "correct" and the suggestion to look at SG voltage yielded a very solid level between RX and TX (not to mention a couple of local hams offering suggestions on 160m last night). I fired it up and said to myself that I'm not going to let this girl go wither on a shelf but figure out what this problem is.

When I was an avionics bench tech (many years ago) we had freezie stuff in a can and I remembered how helpful that was in determining where things were having issues that canned air came to mind.giving a blast of that can frost the circuitry. One blast and it popped right up but instantly went down.

So now I've got a new board on the way and I'll get that component and replace it on my old board then store that one away as a spare. In the meantime I just want to get my favorite girl back on the air!!!!

But really, thanks to everyone for their suggestions. Now to get a sweep signal generator and a spectrum analyzer and maybe I can start a new career.well.anyways.

Subject: [TS-520_820_530_830] Re: TS830S - Strange Behavior - It's Back!

Hello Daniel,

That would be a possible solution if the chip did not have a heat sink
already.

Based on Tate's comments, it appears a previous owner tried to replace the
chip and did a bad job of it. Whether it's possible to "clean" up the mess
the previous owner made, at least for my point of view, is not known. I
would suspect Tate has thought of that and possibly tried cleaning up the
mess. However, if Tate has tried that and no change was seen, then it does
appear the audio IC chip is dragging down the 12VDC supply which is
affecting not only the IF UNIT's Q29 but also other circuits in transmit
plus I also suspect receive circuits as well. Of course Tate can answer
whether he attempted cleaning up the mess from a previous owner.

Not a good idea to use a pipe to protect coax run in it.
you make a nice rodent highway and anything in its way gets attacked.
You are more likely to get coax chewed laying it in a pipe than burying
it without protection.

20890. TS-180s transmit intermittent

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-11 00:29:22 UTC
From: jmpjip
Topic: 20890 Message: 20890

I know this is a hybrid Kenwood group, but my TS-180s is about the right vintage, and thought some of you might have experience with this rig.
Sometimes when I key the TX, all the power is there. Sometimes, there's none. Sometimes, there's a little power that builds to full output in 3 to 5 seconds.

The troubleshooting guide in my service manual points to two different RL1's. One is in the LPF unit, the other is in the IF unit.

Before I dig in too deep, I have two questions:
1. Am I looking in the right direction?
2. Are these relays sealed, or can they be opened up so that I can clean the contacts?
3. Since a relay is an on or off device, what can explain the gradual "ramping up" effect?
     (Oxidation burning through maybe?)

And an unrelated question. Does anyone know of a good mod for monitoring transmit audio?

Thanks for any help you may offer. I've had this radio since 1982, and it has been bulletproof until now. I really like it.

Jim Patterson, K9DXL

Hello Kyke,
The best way to earth your station is to bury as many (and as long as possible) lengths of copper wire just a couple of inches below the earth. Grounding rods are ok for lightning conductors but even a small earth mat makes a more efficient earth than a long earthing rod and its a lot less expensive.-- On Fri, 10/4/09, Kyle <kyle171@...> wrote:

I`ve been licensed since 1988 and have been sitting on my new TS-520 since 1989. I never been in a position to set up my radio, untill now.
I just got me a house with a backyard, although it`s very a very small lot. I hold an Extra Class ticket but I virtually have no experience.
Since I couldn`t get on the air, all I did was study (self taught). Right now I feel like I know nothing. I`m not very tech savy either. I`m a bit overwhelmed in trying to get things set up.
Since my backyard is really small and I`m mostly interested in 80 & 40 meters, I determined that I will set up a verticle antenna.
I don`t know what I`m going to do when it comes to grounding? How does someone with a tiny car get a eight foot ground rod home? Lightning protection, transmission line, etc etc. I guess I have allot of stuff to order and get straitened out before I set up my antenna (which ever that one will end up being). I got moles in the backyard also so I guess I`ll have to run the coax inside of a buried pvc tube. Grrr. To my understanding, moles will chew on the coax cable? I sure could use an elmer right now. The local radio club seems to be a bit unfriendly. About three years ago I went to their Field Day and I was invisible.
Anyhow, I soon will be on the air with the rig. Hopefully it still works? LoL. 73`s Kyle N0MKH

Thanks for all responses. I just finished moving into my new house last weekend so I haven`t had time to do much yet. Grandma left me the house when she SK`d. I hope she doesn`t mind that I have plans to turn her beloved garden into an antenna farm,LoL. I come from an tiny apt that had metal siding. Horrible reception, couldn`t get through. I made a 20 meter dipole that I had strung up along the ceiling. The dipole worked on 10, 15, & 20 meters with my tuner. 1:1 swr on 20. I only made about 5 contacts in five years on it. The dipole will fit fine in the backyard. However I think a 40 & 80 meter dipole would be a challenge to fit in the yard. Yes, a loop should be able to fit. But maybe a challenge to build for me? I do have ALL the books from ARRL. I`ve been studying up as much as I can. Reading & doing is a bit different for me though. Hey, I`m trying though. I also have ALL the Kenwood TS-520 line of accesories. I am anxious to fire up the rig! I also have a FT-857 & an ATAS-120 screwdriver antenna.
Tomarrow I`m going to try an expeirment. I have a huge metal shed in the back yard. I`m going to attach the ATAS to the shed and see what happens. (after sanding the paint down for good grounding). Long story but I never went mobile with the FT-857. I know the ATAS is more of a dummy load than an antenna but I want to just give it a try.
I did have an elmer at one time. He really pushed me into keep studying to upgrade my licensing since I couldn`t get on the air. He SK`d the day I got my Extra. I hope I wasn`t that bad? LoL
Thanks again group. 73`s Kyle N0MKH

I think it's a great FD rig...rugged and forgiving. Just keep the "appliance operators" away from it if your using it at a club station (I lost a set of finals that way a few years ago).

Dynamic range??? What do you think we used for contests before DSP?

Climbing plants love lattice masts, and you'd be amazed how well the addition of some sweet peas can keep the domestic harmony in good fettle.

Just sayin'...

And if you've got an appliance op, teach them how to tune up properly.
They won't be quite so much of an appliance op any more, you get to keep
your finals. Everyone wins.

In regard to coax burial, try burying some PVC or black PVC (used for drainage systems) in a trench. For a really durable installation, line the bottom of the trench with some pea gravel and drill holes in the underside of the PVC for drainage (I've seen a couple PVC runs filled with water causing coax failure)and run your coax inside the PVC. If you oversize the PVC, you can add more cables later on. If you have the means, run at least one additional cable than you need, to use as a spare.

Have fun and feel free to ask questions. If your local club isn't helpful, that's unfortunate, but thanks to the internet, there is lots of help available (sometimes too much...LOL!)

20899. Re: How can I tell if a mixer mosfet is bad? - A happy ending

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-11 21:25:10 UTC
From: chris_yipyap_com
Topic: 20364 Message: 20899

A followup to my story...

This radio was given to my by a ham friend. He got it from a dealer at the Dayton flea market many years ago, also a gift. The thing has had a number of problems, too much to pay a real technician to fix it.

After fixing some power supply stuff, then wrestling with the transmit mixer, eventually figuring out that one of the connectors to the board was bad...

I still wasn't getting much of anything into the driver tube. So, seeing as how I had abused most of the pertinent parts on the RF board over the course of events, unsoldering and trying substitutes, etc. etc., I decided to replace both of the transmit mixer dual gate MOSFET transistors. It was my feeling that one of them was bad and I was limping on one leg, so to speak.

I ordered some from off of Ebay from a guy out of Houston. They are not exactly the same part. I got SK3065s to replace the original 3SK41s. I replaced both of them.

Well, putting those in, low and behold, I have some output now.
I went through the abbreviated coil pack tune up from the "files" section of this site. Some of the coils were off by quite a bit.

Somewhere along the line I also gathered up a couple of Motorola 8298s for the finals. So I neutralized those guys and I'm putting out 80+ watts on 20 meters. I'm just fine with that.

My sidetone is a little fuzzy. And who knows what other bits and pieces could use a touch up. But the knobs are clean, the pots have been sprayed with tuner spray, it appears to be on frequency, the receiver receives and the transmitter transmits.

I'm pretty happy about it!

I've been wanting to get this thing fixed so that I could replace the TS-830 which is my regular rig. That poor guy has intermittent transmit problems which have pretty much made 40 meters unusable.
So now the TS-830 is resting and eventually will go to the bench.

Thanks heaps to many of you who have helped me with advice and information.

Chris w0ep

Hmm, okay. That'll be why so much cable is laid in pipes instead of directly into the ground then - I can put my name to at least a couple of hundred km of UTP, STP, fibre and coax laid in pipe...

Gordon

Thanks for the suggestions.Well it turns out that my ATAS-120 works great with my metal shed. I just made my first contact ever on 40 meters to K4HYB in Georgia (Georgia QSO Party). 59 report. I know this site is about Kenwoods but I`m just happy I`m able to get on the air for a change and made a contact! I have some other odds & ends to take care of but hopefully I`ll have my TS-520 up & running next weekend. Thanks. 73`s Kyle N0MKH

20902. 160 M band is only about 80 watts on ts 8304

Yahoo group: TS-520_820_530_830 (2009)

I have followed the alignment procedures in the manual
and have even properly relaced the tubes. Everything checks out perfect except for the 160 M band which only wants to put out a little over 80 watts.

Any ideas?

The HP 200CD is an audio oscillator and the Heath Q multiplier was used with vintage receivers to improve selectivity I believe. If you don't need them, I'm sure someone on the list would be more than happy to pay postage to take them off your hands. You probably don't have a use for the Heath Q-1, but the HP if it works would be quite useful for troubleshooting or building audio circuits. Too bad bout the tower.

I can say right now that I have no use for these two items. Both seem to be in good condition, however someone cut the power cord off the HP200CD. Copper recycling folks? ya, anybody want them?

Cant resist can you,
IF you had read the original mail you would have read moles
Moles like rats are territorial and will attack any object in their way.
If you put a pipe in the same place as one of their runs and its big
enough for them to get into they will use that instead. Anything inside
the pipe thats in their way will get attacked as well.
If you put cables in a long pipe in the middle of nowhere any
territorial rodents will ignore it as their territories are much larger.
You can not compare the two.

That's why you use a transit block at each end. Of course, if you've got such a massive rodent or mole problem that they're even attacking your conduit, you really need to look at getting some pest control people in.

FWIW, I've always buried my coax in short runs of pipes, down about 18" or so. Despite having quite a lot of moles around, I've never had my coax chewed. Maybe the cats scare them off?

20908. Measuring SSB signals

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-12 12:29:51 UTC
From: James Fogg
Topic: 20908 Message: 20908

My apologies for such a basic question, it was even on my license exam and I've forgotten. I'm returning to the hobby from a very long hiatus and I've forgotten a lot.

I have a TS-530S and a Hitachi 30Mhz oscilloscope. I'd like to display my SSB signal. I'm not sure how to proceed. I could just tap the antenna signal but I'm not sure that's the best way to do it or if a 30Mhz scope is fast enough. I wonder if it may be better to tap a stage prior to the PA's.

I'm experimenting with some microphones on the 530S and would like to see if I'm driving things too hard and any other audio qualities that a scope might display.

Thanks in advance.

Hi Tate, Congrats for the good news ! About repairing the bad board, don't overlook replacing the defunct IC with another audio amplifier with same audio output power, if space is not a problem. I know you need LOTS of luck to find replacement ICs these days... 73's - Daniel, ON5PY

Tate,

The HA-1368R is a 5.3 watt audio amplifier that operates from 13.6VDC. Maximum voltage surge is 40VDC. If you want to download the data sheet, you can get it at the following website:

http://www.datasheetarchive.com/download/?url=http%3A%2F%2Fwww.datasheetarchive.com%2Fpdf-datasheets%2FDatabooks-4%2FBook-29340.pdf

I found the HA-1368 available at the following website for $3.99, no minimum order, in Orlando Florida. I have no experience with this company so you would have to check them out yourself.

http://www.acme-sales.net/portal.php?p_id=HA1368&country=USA

A price of $3.99 is quite a bit cheaper than $30 or more I have seen this chip advertised for on other other website!!!

73
Mike

Hi Jerry. A 30Mhz scope should work just fine. As for a connection, try wrapping about 6 inches or so of hookup wire around the coax. if you son't get enough signal. try a foot of wire or so. Its quick and dirty, but it works with my ancient RCA 5 Mhz scope.

I am sure that if you do some research on the net, you can come up with other ways to connect your scope.

If you don't need them, I'm sure someone on the list would be more than happy to pay postage to take them off your hands. You probably don't have a use for the Heath Q-1, but the HP if it works would be quite useful for troubleshooting or building audio circuits. Too bad bout the tower.

Wow.I've not found them anywhere.that's fantastic. I'll get a few of those
and keep them on hand.

Subject: [TS-520_820_530_830] Re: TS830S - Strange Behavior - It's Back!

Tate,

The HA-1368R is a 5.3 watt audio amplifier that operates from 13.6VDC.
Maximum voltage surge is 40VDC. If you want to download the data sheet, you
can get it at the following website:

http://www.datasheetarchive.com/download/?url=http%3A%2F%2Fwww.datasheetarch
ive.com%2Fpdf-datasheets%2FDatabooks-4%2FBook-29340.pdf

I found the HA-1368 available at the following website for $3.99, no minimum
order, in Orlando Florida. I have no experience with this company so you
would have to check them out yourself.

http://www.acme-sales.net/portal.php?p_id=HA1368
<http://www.acme-sales.net/portal.php?p_id=HA1368&country=USA> &country=USA

A price of $3.99 is quite a bit cheaper than $30 or more I have seen this
chip advertised for on other other website!!!

Chris,

This may seem silly or something we believe hams simply don't do but it does happen, more often than you may think!

OH.now I understand the /R.can't use the 1368 due to the way the device is attached to the heat sink. I'd have to use the /R. The quest continues

Subject: [TS-520_820_530_830] Re: TS830S - Strange Behavior - It's Back!

Tate,

The HA-1368R is a 5.3 watt audio amplifier that operates from 13.6VDC. Maximum voltage surge is 40VDC. If you want to download the data sheet, you can get it at the following website:

http://www.datasheetarchive.com/download/?url=http%3A%2F%2Fwww.datasheetarchive.com%2Fpdf-datasheets%2FDatabooks-4%2FBook-29340.pdf

I found the HA-1368 available at the following website for $3.99, no minimum order, in Orlando Florida. I have no experience with this company so you would have to check them out yourself.

http://www.acme-sales.net/portal.php?p_id=HA1368
<http://www.acme-sales.net/portal.php?p_id=HA1368&country=USA> &country=USA

A price of $3.99 is quite a bit cheaper than $30 or more I have seen this chip advertised for on other other website!!!

The best way to do this is to use an external mechanical relay or an electronic T/R switch. Back in the "good old days" electronic T/R switches were often used to connect a separate transmitter and receiver to one antenna.

Pete,

I agree "IF" this were a separate transmitter and receiver setup but it's not. The separate receive is not being used in conjunction with the TS-520's normal operation.

The separate receiver and it's S meter is used as an indicator while adjusting a transceiver's carrier null controls. Once the TS-520's carrier null controls are adjusted for the lowest S meter reading on the separate receiver, the separate receiver is no longer needed.

I suppose a dow key relay or some other relay setup could be used but, it's easier to use a short length of wire with one end connected to the separate receiver's antenna connection and the other end of the wire placed close to the TS-520's coax. No physical connection to the TS-520 is done, just place next to the 520's coax cable to pick up the signal from the 520, nothing more.

Agreed. I didn't read all the previous posts, so wasn't aware what lead up to the discussion. A simple short antenna lead is all that's needed for this adjustment although I prefer using a scope for carrier null adjustments.

Mike, I suppose I will need a non conductive set of "tunning"
screwdrivers. Correct? I listened to the carrier on my IC-761, and it
was definitely there. Is the carrier supposed to _completely_ go away.
or will I always hear it there a little? (I have not tuned it yet
because I do not have insulated tuning tools yet).

> Pete, wa2cwa
I did the adjustment. I used a 1/4 wave vertical antenna for 220 Mhz as my little sniffer antenna on the other radio. I was able to get the carrier to all but completely disappear on upper and lower sideband. However, all problems remain. The lack of transmit audio I attribute to a bad mic (or mis wired). The mic was a junk box mic that I had never used. I need to find someone in the club that has a known working Kenwood mic to try. I get an audio hum instead of transmit audio, so that tells me that the audio stage is working. It sounds like faulty mic wiring that I hear doing sound at church.

The other issues:

Tone on both sides of the carrier in CW mode only (the correct sideband has a larger signal, but the wrong one is WAY to strong). It works fine listening to CW in USB or LSB mode, I only hear carrier in the correct SB when listening.

In CW mode the CARRIER control is working backwards. I get more power as I turn the carrier knob down. This does not seem to be erratic such as with a dirty pot or something.

Other than that, it is a beautiful rig (9.5 aesthetically). This rig is new to me. I purchased it for $150 at the Salvation Army. I can't wait to get it running to spec, and a CW filter for it.

Thanks,
Chris KQ6UP

>
> Adjust the 9VDC "FIRST" then adjust the 3.3VDC. The above adjustments are found in the TS-520S service manual on page 45 "RECEIVER SECTION" at paragraph "2" titled "SETTING THE 9 VOLT POWER SUPPLY and FET BIAS SUPPLY VOLTAGE". The 9VDC powers not only the VFO, both internal and, if used, external, plus a number of other circuits. The 9VDC flows through the FUNCTION switch AND pins 8 and 9 on the rear 9 pin external VFO socket. Clean the FUNCTION switch with contact cleaner (DeoXit) and ensure the connection at the rear 9 pin VFO socket are clean and secure. Clean the plugs that plug into the rear of the VFO.

I did the carrier balance before I did the voltage adjustments. I guess
I will probably have to null the carrier again after making the voltage
adjustments. I am also assuming that the carrier balance for U and LSB

is not going to effect how the CARRIER knob works, but the voltage adjustment might fix the issue.

Thanks,
Chris KQ6UP

20924. TS-820S RF Board

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-13 04:08:30 UTC
From: jsloss
Topic: 20924 Message: 20924

My 820's RF board is acting up w/ no ALC reading in TUNE, weak crystal calibrator signal on all bands, and there may be more. Have isolated problems to this board by board substitutions.

I wonder if anyone is set up to service this board while it is in a working 820S. I suspect the culprit is in the ALC and or Mixer components. Hate to arbitrarily replace parts.

Another option would be to find a good RF board that is available.

Thanks,

Joe k7mks

Topic: 20924 Message: 20925

Hello Joe,

In TUNE mode, missing ALC can normally be traced to defective resistors R5 and R6 on the HV UNIT. Check and, if necessary, replace both R5 and R6 (both are 56K 1/2 watt).

It's possible that Q2 and possibly Q3 on the RF UNIT are being partially cut off in receive. Check Q2 and Q3's G1 voltage in receive. It should be as follows:

Q2 G1
+2VDC (receive)
-3.5VDC (transmit)

Q3 G1
+2.1VDC (receive)
-3.3VDC (transmit)

A less positive or even slightly negative voltage on Q2 and/or Q3's G1 pin can significantly reduce Q2 and/or Q3's ability to amplify an incoming or Marker signal appearing at Q2's G1 pin.

Also check Q2's Drain voltage. Measure this at the RF UNIT's "MD" pin and ground. Band switch and MODE settings does not matter. It should be as follows:

+13.5VDC (receive)
+12.8VDC (transmit)

You can also inject a signal at the junction of C24 and R45 on the RF UNIT. Keep the signal level low so as not to over drive Q3. If this produces an S9 plus S meter reading then it's quite possible that either Q2 is bad or Q2's associated components have failed.

An improperly adjusted T2, the RF UNIT's receiver mixer (Q6 and Q7) output transformer can significantly affect the level of "RIF" signal (8.830Mhz) that is fed to the IF UNIT.

Mike:

Both R5 and R6 are OK as another RF board I have works just fine in this 820.

Thanks for your thoughts on the weak receive. This board has either one or two problems:

1 There is something that is causing loss of ALC reading in XMT and loss of signal in RCVE...or

2 There are two problems with one associated with the ALC and one associated with weak receive.

Back to the drawing board. Plugging in a known good RF board into this 820 corrects both problems.

Joe

You must connect you oscilloscope probe across a 50 ohm dummy load then calculate the power output using - P(out)=V2/8R (power out equals V squared divided by 8 X 50). Where P = peak to peak voltage. (ie where peak to peak voltage = 100 then 10000/400 = 25W). --- In TS-520_820_530_830@yahoogroups.com, "James Fogg" <james@...> wrote:

Hi Joe,

Q5 on the RF UNIT is the ALC amplifier. If Q5 is bad there will be no ALC in TUNE, USB, or LSB. ALC isn't used in CW mode so there will not be any indication of ALC at any power output level (CAR setting) in CW mode.

Check Q5 on the RF UNIT, I suspect it's bad.

I don`t remember when or where but I believe I have read some where that if you have moles, squirils, rabbits, and any other rodents in your yard they have a tendency to chew on your coax. None of the less I`m going to have to bury the cable especially before I break out the lawn mower or before I trip myself again. I like the idea burying the coax inside of pvc tube. I`m not sure what transit blocks are? But I was thinking of where the coax enters & exit the pvc tube I will have something like a sink trap (upside down j figure)and devise a way to keep any rodents and water from getting in. Of course the pvc tube will be big enough to add an extra coax or two for an additional antennas. Someone suggested that I drill a few small holes on the bottom of the tube for water drainage. It`s about 30ft from antenna to shack in a strait line. I wish I had one of those ditch digger machines:)
I`m wondering how hard it will be to string a good quality coax thru the tube when or if I`1l be needing to? Right now I`m usuing cheap radio shack (rg-58?) coax laying on the ground but will be replacing that when ever I get around to it. Although it`s working fine for now.
Thx for suggestions. Kyle N0MKH

I haven't experienced this with Ken but I have experienced it quite often with others.

Unfortunately, it's a shame this type of behavior occurs everyday, especially in a world dominated by electronic communications (cell phones, instant text messaging, or e-mail). There is no excuse, unless one is incapacitated or dead, for not responding in a timely manner.

Good luck.

20936. Mic Recomendations

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-14 17:10:35 UTC
From: Chris Maness
Topic: 20936 Message: 20936

I have a junk box shure 444d that I wired up to work with the TS-520s. However, I just get the sound of hum when I listen with an adjacent reciever. I imagine that the mis is eaither wired incorrectly or broken. The radio is new to me so I am not totally sure there is not a problem with the transmit audio. Does someone live in the socal area to loan or sell a cheap microphone for my TS-520, or is there an inexpensive ebay recomendation.

Help... I love this radio on CW, and would like to get it working on SSB too.

Thanks,
Chris KQ6UP

Mark,

Everything I'm seeing on the net the MC-50 is going for around $100 plus shipping. let me know what you think. Thanks for asking

Hi John

I am after the MC-50 mic to complete my set up in the shack if it is still availible. what do you want for it? set a price.

regards
Mark

I do not have the knowledge to work with these rigs and to be honest it wasn't very nice of me to get them in the first place. This group has been a wealth of knowledge for me but I'm honestly out of my league with these radio. I would like to sell it all together, but will divide if need be. Equipment goes to individual who makes best offer, plus shipping. Thanks for your time and please contact me off group and I will have pictures to send.

20939. Re: Strange issue with the carrier controll

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-14 23:19:53 UTC
From: w5rkl
Topic: 20746 Message: 20939

Chris,

This is a repeat, sorta, of my reply to your private e-mail.

Yes, the 9VDC adjustment will affect the carrier null adjustment. The balance modulator's DC voltage depends on the 9VDC source being right "before" adjusting the carrier null. If the carrier null adjustment is performed before the 9VDC is adjusted, any carrier null adjustments will be null and void and you will have to be redone carrier null adjustments after adjusting the 9VDC.

So why perform the 9VDC before the 3.3VDC? It's simple, the 3.3VDC is obtained from the 9VDC. If the 3.3VDC is adjusted first then the 9VDC, again, the 3.3VDC is "null and void" and you will have to redo the 3.3VDC adjustment. So do the 9VDC adjustment then the 3.3VDC.

Adjusting these two voltages is important since so many circuits rely on them to operate properly. For example, if the 9VDC is not right, less than or more than 9VDC, the VFO will be off frequency. A drifting 9VDC supply is the primary cause of drift in the 520 and 820 since the VFO is an "analog" device. Any change in the 9VDC power source to the VFO will affect the VFO's stability. As components age, voltage drift occurs, usually in the 6.1 zener diode, WZ-061 and current limiting transistor, a 2SA496Y, on the AF UNIT in the 820 and a 2SA606L, on the FIX CH UNIT in the 520. I had this problem with my 820 and replaced the 2SA496Y plus the zener diode which, after normal warm up, reduced drift to factory specs with the 9VDC and 3.3VDC adjusted properly.

The CW issue is most likely caused by the CW CAR UNIT crystal being OFF FREQUENCY. When this occurs you will experience problems such as you are having in CW receive and most likley cause a reduction in CW output power. If the CW CAR UNIT crystal is off frequency, the RF signal is place improperly in the filter's bandpass which affects the level of signal coming out of the crystal filter. A reduction in RF signal at the output of the crystal filter cannot be fixed by advancing the CAR control. The fix is to check and, if necessary, adjust the CAR UNIT's CW crystal so it produces a "3395.0Khz" signal. I think I said 3395.0 "Mhz" wiich is wrong. I should have said "Khz" which would be right. I apologize for that mistake.

Since USB and LSB are fine do not mess with USB or LSB GEN UNIT crystal adjustments "TC-2" or "TC-3".

You will need a frequency counter to determine how far off the CW GEN UNIT crystal is. Perform the following steps.

1. Connect the 520 to a dummy load
2. Connect the frequency counter to the GEN UNIT's "OUT" connection
3. Set the CAR control to minimum
4. Remove any CW key from the rear CW socket
5. Set the MODE switch to CW

Power up the 520 and allow it to warm up for a minimum of 30 minutes. Flip the "SEND" switch "UP" and note the frequency counter reading. If it's not "3395.0Mhz" locate and adjust "TC-1" on the GEN UNIT so the frequency counter reads "3395.0Mhz" then flip the SEND switch "DOWN". This should fix your CW receive problem plus if the 520 had low output in CW, the output power should be good now.

Remember, the GEN UNIT provides the individual BFO frequencies for USB, LSB, or CW receive. If any of the GEN UNIT crystal oscillators are "OFF FREUENCY" the receiver will be affected. Again, since USB and LSB work fine do NOT mess with TC-2 or TC-3 on the GEN UNIT. If you mess with TC-2 or TC-3, USB or LSB will be affected in both transmit and receive.

Let us know how things turn out.

The above adjustments are found in the TS-520S service manual on page 45 "RECEIVER SECTION" at paragraph "2" titled "SETTING THE 9 VOLT POWER SUPPLY and FET BIAS SUPPLY VOLTAGE". The 9VDC powers not only the VFO, both internal and, if used, external, plus a number of other circuits. The 9VDC flows through the FUNCTION switch AND pins 8 and 9 on the rear 9 pin external VFO socket. Clean the FUNCTION switch with contact cleaner (DeoXit) and ensure the connection at the rear 9 pin VFO socket are clean and secure. Clean the plugs that plug into the rear of the VFO.

20941. TX Audio Super Distorted

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-15 04:22:27 UTC
From: Christopher Maness
Topic: 20941 Message: 20941

I was able to barrow a known working mic from a local ham. If I transmit into a dummy load and recieve on a near by X-miter, my transmitter audio is extremely distorted. This is if adjust for the correct readings on the ALC. My previous mic was not working at all, but this one is giving me ALC deflection. This is a stock hand held mic that was shipped with TS-520s.

Any suggestions?

Thanks,
Chris KQ6UP

Hello Chris,

I "think" I understand what you mean when you say,

"This is adjust for the correct readings on the ALC."

Are you saying that you adjust the MIC gain to a point where there is a constant ALC meter indication during sideband transmission?

Although the manual states the ALC meter indication, during sideband transmission, should be kept within the ALC meter scale, that does NOT mean you have to set the MIC gain so there is a "constant" ALC indication during sideband transmissions!

As for your distortion problem, here's a simple test you can perform to determine if the speech amplifier is producing distortion on its own. Remove the microphone completely. Turn the MIC gain to minimum. Looking at the MIC socket you will notice "4" pins, one bottom left, one top left, one bottom right, and one top right. Use a screw driver or jumper wire, short the "top right" pin to the MIC socket shell. This is the PTT circuit and will key the transmit. If the distorted signal is not heard in the separate receiver, slowly advance the MIC gain to the point you normally set it at. If the distortion is no longer heard in the separate receiver, the distortion problem more than likely not caused by the 520.

Here's another test you can do. Place the 520 in TUNE mode, set the CAR control to minimum and key the transmitter with the "SEND" switch while listen to your signal on your separate receiver. Slowly advance the CAR control. Do you hear distortion or hum in the separate receiver? Again, if not, the problem is most likely not in the 520.

The Kenwood hyrbrid operating manuals clearly show the PTT ground return must not be connected to the microphone ground return. The ground returns must be separate.

The two test indicated above should be conducted with the 520 connected to a dummy load.

Has anyone developed a way to measure voltages on Q2 and Q3 in the RF board when it is installed in the 820? About the only way I figure it can be done is to fabricate extender boards for the 3 4-pin connectors that are on the coil pack board. Anyone have a scrap coil pack board they don't need? I'd also settle for a RF board that works then I won't have to troubleshoot this one!

Hello,
my call sign is old but I got back into this hobby last year and dragged my hubby into it as well. along with this was unpacking my TS-520 that I acquired back in 1985. it has essentially been sitting in the closet for all this time.
 back in the day, time antenna tuners were not in the picture in I happily dipped and tuned my rig to tx. I am now being told I should get a separate tuner by those with higher class lic than me.
what do you all recommend for this rig?
currently I have 2 home brew wire dipole antennas. one for 40 m, and 80 m.. the 80 m is an inverted V.
thank you for your input.

Christy,

I use an MFJ 949e with my 520s. The tuner is extremely versatile, having a 4:1 balun, two coax connections, a random wire connection, and a balanced line connection all built in. It also has a forward power/SWR meter and backlighting if so desired. I have fun with it sometimes just loading up random objects. I made 40m PSK contacts off of an aluminum canoe in my back yard. I've heard of people loading up lawn chairs, rain gutters, etc. with this and similar MFJ tuners.

They are built to take around 300w, so if you are running high power, look elsewhere.

Have fun!

Hi Christy,

The pi net in your transceiver likely already has a Z matching range of close to 3:1. Considering you are using monoband dipoles, I don't see the need for a tuner.

The newbie hams (despite their license class) may not have a clue about vacuum tube finals and output matching networks.

Hello Christy:

I would recommend the MFJ 949E Deluxe Versa Tuner 2.
It has a 100W dummy load, cross needle lighted SWR/POWER meter, (the light in the meter is powered by a small power supply, optional). Three antenna positions, two coaxial and one wire. Also has average and peak power readings (the peak reading is not true pep, but there are filter caps in the circuit, that slow the meter swing down some to for easier SSB power readings). The meter also has high and low
power settings, 100/300 watts. The tuner is equipped with a Balun. You can also bypass the tuner, and
run direct to the antenna, with a flip of a switch. I have two of these and have used them daily for 15 years, with no problems. Hope this helps 73, gary n0tqq.

Hello,
my call sign is old but I got back into this hobby last year and dragged my hubby into it as well. along with this was unpacking my TS-520 that I acquired back in 1985. it has essentially been sitting in the closet for all this time.
back in the day, time antenna tuners were not in the picture in I happily dipped and tuned my rig to tx. I am now being told I should get a separate tuner by those with higher class lic than me.
what do you all recommend for this rig?
currently I have 2 home brew wire dipole antennas. one for 40 m, and 80 m.. the 80 m is an inverted V.
thank you for your input.
Christy

Hi Christy,

The tank circuit in the 520 will happily match anything up to a 3:1
VSWR. If your aerials and radio worked well together back in '85
they'll do the same now. If you intend to stick with the two dipoles
and the radio loads up well I see no point in getting a tuner.
However, there's plenty of good tuners out there and you'll have
plenty of good advice on which make/model will suit your requirements best.

Welcome back.

>
This is correct.
> Although the manual states the ALC meter indication, during sideband transmission, should be kept within the ALC meter scale, that does NOT mean you have to set the MIC gain so there is a "constant" ALC indication during sideband transmissions!
>
It more or less tickles the ALC.
> As for your distortion problem, here's a simple test you can perform to determine if the speech amplifier is producing distortion on its own. Remove the microphone completely. Turn the MIC gain to minimum. Looking at the MIC socket you will notice "4" pins, one bottom left, one top left, one bottom right, and one top right. Use a screw driver or jumper wire, short the "top right" pin to the MIC socket shell. This is the PTT circuit and will key the transmit. If the distorted signal is not heard in the separate receiver, slowly advance the MIC gain to the point you normally set it at. If the distortion is no longer heard in the separate receiver, the distortion problem more than likely not caused by the 520.
>
I now have a different mic than the 444D. With the 444D I just was able
to get hum when I cranked up the mic gain. A local ham loaned me the
OEM hand mic for his 520S. This works a little better. I get audio and
ALC deflection. However, the audio with this mic conected sounds
distorted, and it drops off a little if I test it with "loud" audio as
opposed just regularly saying test. I don't think it is the driver tube
or the finals, because I get constant power output in CW.

Jumpering the PTT gave no hum or distortion sounds even with GAIN 100%.
> Here's another test you can do. Place the 520 in TUNE mode, set the CAR control to minimum and key the transmitter with the "SEND" switch while listen to your signal on your separate receiver. Slowly advance the CAR control. Do you hear distortion or hum in the separate receiver? Again, if not, the problem is most likely not in the 520.
>
This gives me a carrier at CAR=0 but drops off just like the CW power
does at CAR=1 when I am in CW mode. I need to still do those voltage
measurements.
> The Kenwood hyrbrid operating manuals clearly show the PTT ground return must not be connected to the microphone ground return. The ground returns must be separate.
>

Stock mic. My buddy has another OEM desk mic. I might give that one a
shot too.

Chris, have you checked the CW CAR UNIT frequency yet? If not then perform the 9VDC and 3.3VDC adjustments then check the CW CAR UNIT frequency. Instructions on how to check and adjust the CAR UNIT were included in an earlier post/e-mail.

Hi All,

I am in need of a small fix.
My TS-830S seems to read 1Khz lower then it should. I have checked this against my other 2x HF radios, a TS-480S/AT and TS-450S/AT

When I am on a freq, say 14.260Mhz I will have to tune it to 14.259Mhz, the other radios are bang-on 14.260Mhz.
It does not change if I change it to 80mtrs, still have to tune 1Khz lower to get a good solid audio.

The TS-450S has now gone and the TS-480S/AT is going back in my vehicle soon. So the TS-830S will be my main home radio.
It's not really a problem, I can tune it okay, but if I can fix it I would like to.

Regards

Kevin, ZL1KFM.

Hi Kevin. Have you trued the Digital Display calibration (page 21 of the manual, section 4.6)? On quit a few of the radios that I have owned, there has been the annoying (to me) problem that when stations are tuned in correctly, it was at the point that the display would flicker between say (for example) 14.299, and 14.300 when tuned in on 14.300. A slight adjustment of the Digital Display cured this problem on my TS-530S.

I like to have the radio tuned in to where it is just past the point where the digits flicker in the manner described above.

I borrowed an MFJ-949 tuner which was pretty good after a few dodgy solder joints were cleaned up. It seems a bit finicky and sensitive to hand capacitance on 160m, but the TS-520 doesn't have that so I never found it to be a problem.

> currently I have 2 home brew wire dipole antennas. one for 40 m, and 80 m.. the 80 m is an inverted V.
> thank you for your input.

I now use a wire dipole for 20m and a loaded wire dipole for 40m (don't have room for 80), with no tuner. The pi network in the TS-520 has more than enough range to tune these. If you've made it properly, the antenna should be just about the right load anyway.

Gordon

Just a thought, if you're using CW mode the frequency indicated will be offset by the beat frequency of 800hz, i.e. if you wish to listen on 7020khz for example, you'd dial up 7019.2khz, and this is correct (it should indicate 7020khz on key down in this case).

Perhaps this is what you're observing?

Cheers

Hello Christy,

Thought I'd chip in with this one too, seeing as I'm currently bored and none of the other posters have mentioned dummy loads.

Seeing as our favourite Kenwoods have impedance matching already built in, you really need to have a reliable starting point when using external antenna tuners, otherwise there's a lot of knobs to twiddle and it'll get confusing, and the correct way to do this is to tune your TS-520 into a 50 ohm dummy load first, then switch in your antenna and tuner and tune that to get a match.

I think there's at least one MFJ tuner that has a built in dummy load expressly for this scenario and I'm sure there are others too.

Otherwise I concur with other posters, with your tuned dipoles you really don't need one unless you're trying to tune odd lengths of wire, or pieces of furniture as others have indicated, or in my case an untuned balanced doublet.

We're not saying that your advisors are wrong, and for sure any and every effort towards interference suppression is greatly encouraged, a low pass filter in your feedline is always a good idea, but PI tank in these radios is well designed, so it's fine to carry on as you always did.

Welcome back to the hobby and enjoy !!

Chris,

Although I do not recommend using an IC-761 to set the 520's CW UNIT crystal frequency (zero beat the 520's CW CAR UNIT crystal frequency at 3395.0Khz on the IC-761), if that's all you have you could try it. However, understand the accuracy of the CW CAR UNIT crystal adjustment will be quite a bit more accurate using a frequency counter.

I am aware that a frequency counter's accuracy is based entirely on the accuracy of the counter's base reference crystal.

The key is to adjust the 520's CW CAR UNIT crystal oscillator frequency to 3395.0Khz so its signal falls in the proper position in the crystal filter's bandpass.

Regardless of the method you use, make sure you allow the 520 to warm up for a minimum of 30 minutes before attempting any of the adjustments. Then, after the warm up period, perform the adjustments in the follow order.

1. Voltage adjustment (9VDC "first" then the 3.3VDC)
2. CW CAR UNIT adjustment (3395.0Khz)
3. Carrier null

Note:
Make sure you are adjusting "TC-1" and NOT TC-3 or TC-3, on the 520's GEN UNIT!

If you use a small metal screw driver and notice the CW GEN UNIT's crystal frequency change as you bring the screw driver close to the oscillator's adjusting capacitor, find or buy
a non-metal adjusting tool. I believe, but I'm not certain, that Radio Shack sells a non-metalic alignment set which may contain the tool you need to make this adjustment. I do know Radio Daze sells a complete alignment tool set, www.radiodaze.com, because I bought mine from them.

Performing these adjustments "should" fix your CW and CAR problem. However, as I stated earlier on, there may be other problems you have not yet found.

Let us know the results.

Hi Christy,
I use a Kenwood AT-200 tuner with a TS-520SE. It's nice to be able to switch between two different antennas and a dummy load without messing with cables and it's good to confirm power out. And it looks good.

Hello Kevin,

Although it is possible the digital display calibration may be the problem, I have to first ask a question.

When you tune the 830 to 14.260Mhz do the voices sound "natural"?

If the voices do not sound natural at 14.260Mhz but the voice sound natural at 14.259Mhz then it appears the problem is not a digital display calibration issue but rather the 830's standard reference oscillator may be off frequency. See the 830 service manual's circuit description section starting on page 3 and adjustments starting on page 32 for further details.

I had purchased a TV alignment kit from radio shack. The shafts are
plastic, but the blade has a small amount of metal for strength.
Hopefully the small size of just the blade part will keep it from
drifting. My Icom has the Xstal oven in it, and I think if I
re-calibrate it to WWV it should be pretty good. When I tune to DX
spots, they are dead on frequency. I will give it a shot.

Thanks,
Chris KQ6UP

Hi Christy,
Your radio has an internal tuner. If your dipoles are well balanced and resonant with low SWR,
don't waste your money.
If you still want one, it's very easy to build.

The small metal blade you are talking about in the alignment tool should not be an issue.

Hi Christy,
You may not need a tuner, just a little more wire.

You already have 80 covered...

The 40 dipole will work on 15 at the 3rd harmonic. So all you need now is 20 & 10. Go add these to the 40M dipole feedpoint and make a fan/parallel dipole. You will need about 50' of wire which may be cheaper than a tuner.

Now if you still need/want a small tuner keep your eyes peeled for what ever fits your budget. However I recommend the Dentron Jr Monitor for small tuners. If you want something that is a auto-tuner I would highly recommend the SGC-239, best tuner I have ever used since it stores the tuned freq settings to memory. It never has to retune, pretty much throw low signal at it and its tuned in 1 second.

Anyways I still recommend something resonant with out using a tuner unless you have no other options. The only reason I use a tuner now is because my main ant is a 160M Loop and I use it 160 - 6.

Regards,
Aaron

Cristy,

No need for a separate antennatuner with the antenna's that you are using, dipoles have a impedance near 70 ohms that can easely tuned with the tuning network in your 520.

Only if you go far from the design frequency of the dipoles, you can need a tuner.

A common misunderstanding for the need of a tuner is that you can use every piece of wire to transmit, but there is no better antenna than a dipole or other antenna, that resonates on the working frequency.
All others are just a compromise and a tuner helps the transmitter to "see" a proper load, but the non-resonant antenna is just as bad as before.
Many use a "magic" antenna with a chicken feeder and a tuner, they get it in resonance, but do not understand that in that case a reasonable portion of the feeder is working as antenna, that radiates too, with unpleasant results as TVI and BCI problems.

I think you have a couple of good antenna's for the time beiing.
Have fun, and welcome back.

Hi Chris,

VR2 is part of the RIT circuit and is used to adjust the zero point
for the control. Follow the RIT alignment procedure on page 48 of
the service manual and you'll be back on track.

OK, done. All values were out of spec. The voltages were too low. The TC1 was off freq. The carrier balance needed re tweaking. However, after I made all adjustments.

CW beats still heard on both sides of the carrier.
CARRIER knob stills only goes to full power when the knob is turned below 1 (but still not quite full output).
SSB Still hideously distorted when gain is turned up (even just to 3 with no compressor).

I am a little discouraged. Seems like such a beautiful radio seems to be a bit of a basket case. No wonder some one donated it to the salvation army ;o)

However, I am hard headed and want to get the ol' gal running again.

Any advice?

Thanks,
Chris KQ6UP

20974. Do TS530 radios have cathode resistors on the PA tubes?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-17 02:47:32 UTC
From: hczerwick
Topic: 20974 Message: 20974

I've got a radio on my bench, it's not mine. The owner was under the impression that one of the power amp tubes needed replacement. So he bought a pair of tubes off of ebay. One of the tubes had the index pin broken off of it. Well now that I've got the full story he inadvertently put this tube in rotated one pin off. So I guess the first time he keyed the mic he let the smoke out so to speak. Before I got the whole story from him I was looking at a radio with no output, which I've heard can be a result of the Cathode Resistors being open or out of value. I see illustrations around on the location and how to check these resistors on the 830 radios but I've found nothing on such resistors on the 530. Are they there or is there something else I should look at on this radio? If it's not solved in a week or so I button it up and it goes back.

Thanks AB2XG

Hi. The TS-530S does indeed have cathode resisters. All the tinal
sections of the Kenwood hybrids are very similar.
See http://www.k4eaa.com/ for more information. You will also find
parts there.

Good Luck!

Chris,

I have to wonder how "clean" the 14VDC supply is?

AC ripple on a DC voltage applied to the balance modulator can cause a balance modulator to become "unbalanced", producing irregular output even with the CAR control set to minimum.

I had a similar problem with an old Hallicrafter FPM-300 when a LV filter capacitor failed. AC ripple was causing the balance modulator to become "unbalanced" and no matter what setting the Drive control was set at, RF appeared at the balance modulator's output. Replacing the failed capacitor fixed the problem. I can't say for sure this "is" your problem. I just wonder how clean the 520's 14VDC supply is since it provides the voltage for quite a number of circuits, including the CAR control's variable 9VDC that controls the balance modulator in CW/TUNE modes plus the DC operating voltage for the speech amplifier, as well as quite a numer of other circuits.

If you have, or can borrow, an oscilloscope, connect the scope to the FIX CH AVR UNIT's pin labeled "14". If there is evidence of AC ripple, replace C21 and C22 with the same capacitance value "BUT" with a higher voltage rating of 25VDC. Kenwood recognised this in the 530, 820, and 830 series as the 14VDC filter capacitors in all 3 of these series now have a working voltage of 25VDC not 16VDC. A 16VDC rated capacitor in a 14VDC supply simply does not provide a sufficient maximum voltage safety margin.

Although I can't say for sure, Radio Shack "may" have 2200ufd 25VDC capacitors. Use axial lead caps but radial lead caps will work just fine, they just won't mount the same as axial lead caps will. Just ensure the cap voltage rating is 25VDC or higher and at the same capacitance, 2200ufd.

"IF" you replace C21 and C22, go back and redo the 9VDC and 3.3VDC adjustments. You may also have to redo the carrier null adjustment and, while you're at it, check and, if necessary, adjust the CW/TUNE CAR UNIT TC-1 crystal adjustment so the frequency is 3395.0Khz.

From: w5rkl
Topic: 20974 Message: 20977

Yes, the 530, like all the other hybrids, have cathode resistors. The 530 has "4" of the, R3, R4, R5, and R6, all "20 ohm 1/2 watt". They are located on the bottom of the 530's FINAL UNIT's PC board.

If the final tubes were inserted "1 pin off", it is likely these resistors were damaged. However, I would NOT look ONLY for damage to the cathode resistors, I would also look at the Rectifier Unit for damaged components as well as damage to the HV Unit components.

Depending on which pins were in the wrong socket holes can mean damage occurred in one or more areas so don't simply look for damaged cathode resistors. Inspect the RECTIFIER UNIT and the HV UNIT for damaged components plus inspect each board plug for overheating due to high current flow through the plug. A shorted plug can cause other problems that may not be evident at first glance.

If you do not have the 530's operating and service manuals, I recommend obtaining them before proceeding with any repairs. You can download them free at the following website.

Ken, K4EAA suggested that I tune for actual center of the IF passband.
He stated that the SSB filter might be out of spec, and tuning for
the correct passband does make sense, as the CW passband actually
sounded a little worse after I zero beat the CAR with the 761.

Here is the full response that Ken made. Just wondering what you
think about it:

Hi Chris;

It sounds like you're missing a ground connection at your MIC/CAR
pots. A quick check with an ohmmeter should verify that.

The CW signal should be offset by 700Hz. You can pretty easily tune
it by ear so 700Hz peaks in the center of the passband of your CW
filter. If you only have an SSB filter, adjust it like you would the
USB and LSB carrier frequencies - Use the calibrator and adjust for
the lower corner frequency around 100Hz or so. The carrier
frequencies depend on the actual passband frequencies of the filters
installed, so they are not usually set to "spot on" frequencies, but

rather so that the signal is placed into the passband of the specific filter(s) properly.

Remember that because your 520S uses shared transceiver circuitry, what you hear on receive is what you'll sound like on transmit as well. That makes it simple!
Hope this helps,
Best 73's,
Ken

> I've got a radio on my bench, it's not mine. The owner was under the impression that one of the power amp tubes needed replacement. So he bought a pair of tubes off of ebay. One of the tubes had the index pin broken off of it. Well now that I've got the full story he inadvertently put this tube in rotated one pin off. So I guess the first time he keyed the mic he let the smoke out so to speak. Before I got the whole story from him I was looking at a radio with no output, which I've heard can be a result of the Cathode Resistors being open or out of value. I see illustrations around on the location and how to check these resistors on the 830 radios but I've found nothing on such resistors on the 530. Are they there or is there something else I should look at on this radio? If it's not solved in a week or so I button it up and it goes back.

> Thanks AB2XG

Yes, the 530 has fuse resistors.

The 520 has two, ten ohms each. Is there any reason for using four at
20 ohms? Is it a modification worth making?

Damaged sockets, even. I can't see how it's possible to fit an octal
valve "one pin off" without the aid of a hammer.

Bear in mind that the cathode connection is broken out to three pins on
the valve base. Depending on which way round the valve was inserted
wrongly, it could either have shorted the heater supply and control grid
connections, or (potentially more seriously) connected the screen grid
and control grid connections, stuffing several hundred volts into the
bias supply through a couple of rather small RF chokes.

Gordon,

Notice the subject, "TS-530", not "TS-520" and yes, the "530" does have "4" cathode resistors, R2, R3, R4, and R5, each 20 ohms at 1/2 watt, wire in parallel.

Gordon,

The original post stated "one" of the final tube's center plastic "guide pin" was broken off. If the center guide pin is broken off, missing, the tube can be inserted in the socket any way the person inserts it. The tube can be rotated 180 degrees and the tube will still insert into the socket quite easily.

Yes, I know. I've got a TS-520, which has two, and I've repaired a couple of TS-530s, which have four. What I was asking was, is there a good reason for using four in the later radio, and is it worth replacing the two 10-ohm resistors with four 20-ohm resistors? Presumably they changed it for a reason - the rest of the PA is pretty similar.

The only thing I can think of is that it's more likely to fail "softer" and operate with degraded performance with three resistors, if one fails.

Ah, that makes sense. I'm surprised that breaking that didn't break the
valve seal, which extends down into the locating pin.

Gordon,

For what ever reason Kenwood used 4 cathode resistors, the end result in resistance is the same 5 ohms.

p.s. I tried every position on the carrier TC for CW (all 360 deg), and none completely eliminated the unwanted sideband. I am now wondering if the LO crystal is out of spec. I want to CC the group so as to keep a running log of what I did in case another poor chap needs this thread.

I also second the feeling on the CB hacks. I have a FT-101E that I got several years ago. It was my first full 100watt ham radio. The 10m A section xtal had been subbed out for lame Chicken Band "freebanders." However, in ordering a new xtal, I found the xtal manufacturer was right around the corner from my job, and I got a factory tour of an xtal manufacturer plant.

I was looking over the schematic this morning and figured that is how it works. What is strange to me, is how I could get the LO Xstal to vary about 2K with TC1, but the receive frequency was not varying by the same amount. It seems that if one varied (since mixing is addition or subtraction not multiplication) then it should vary by the same amount. I need to find a local elmer with some good test equipment. All I have is an oscilloscope, DVM, and a calibrated receiver. I miss my friend Rich AB4AW. He worked in commercial two way radio, and had everything. That is how I got my FT-101E lined up.

Chris,

The reason you only hear a ~700Hz instead of ~ 2Khz is how the 520's balanced ring detector circuit on the Generator Unit is configured/arranged. However, this is how I interpret how the balance ring detector on the 520's Generator Unit works. A balance ring detector compares the two RD1 and RD2 signals.

If you look at the 520's IF UNIT, notice RD1 and RD2 signals. RD1 is the "positive" point of T6 while RD2 is the "negative" point of T6. Both signals are fed to the balance ring detector diodes, D9 thru D12, but only one output signal, after mixing with the Car Unit signal, will be fed to the audio amplifier. That limits the swing ~700Hz instead of ~2Khz you hear on the separate receiver.

This may not be "exactly" correct but that's how I interpret how a balanced ring detector works. Ken may set me straight on this and/or correct any deficiencies I have in my understanding of how this all works.

I meant to say, "only one of the RD1 or RD2 signals will produce an output from the balanced ring detector to the audio amplifier".

Again, I could be wrong or only partial correct on this.

I will have to study this out too. Actually changing TC1 (CARRIER BOARD) only effects the MARKER tone by about 30~50Hz. Also, the switching diode that inserts and removes a capacitor to go from CW RX to CW TX is supposed to move the LO (CAR) by 700Hz for the tone offset of CW. My rig is only actually changing the LO (CAR) by ~300Hz (maybe the CARRIER board needs some parts replaced). There is something wrong there. Also, I think a change of 2kHz for the LO should equal a change of 2kHz in the IF. Otherwise, when the switching diode changes the 700Hz between RX/TX in CW, there would not be enough of a shift for a CW offset.

I am having fun trying to fix this. It was very frustrating at first because I am impatient, and want to fix the thing in one shot. I remember it took some patients working on my Ol' FT-101E too. Especially since a CBer had gotten a hold of it.

Thanks guys,

20995. TS-820s audio out low

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-19 18:21:43 UTC
From: Kevin Rea
Topic: 20995 Message: 20995

hi guys,
I have a 820s and the audio/microphone gain needs to be turned up all the way. I have the compression off. in fact, if i use the compression, it does not increase it at all.

I am using an mc-60 microphone that is in good working order.

what should I check to increase the audio on this rig ?

thanks,
Kevin Rea

how are suppling voltage to mc-60 (do you have an internal battery), how
does it do on a stock hand mike... did you rewire the mc60 or using 8 pin to
4 pin adapter (check that)

if it is ok on hand mike, then I would suspect the mike still.

the mc-60 has internal battery.
i have tried 4 different microphones..
they all give the same result.
i have to have the mike gain up full and speak very loudly
at the mike screen.

Hello Kevin,

Set the MIC gain at 9 o'clock, VOX gain at 9 o'clock, then flip the VOX switch up. Speak normally into the microphone. If VOX trips, keys the transmitter with the above settings, the speech amplifier is working properly.

If the above setting does not make VOX key the transmitter and you have to turn the MIC gain setting and VOX gain setting to the settings you mentioned then I would suspect the problem is in the speech amplifier.

20999. CARRIER Board and Balanced Modulator Theory of Operation?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-20 16:14:20 UTC
From: Chris Maness
Topic: 20999 Message: 20999

I wanted to finish our discussion on the theory of operation of the carrier board, so that I can make sure that I understand it correctly. You had suggested that a 2k shift in LO frequency on the CARRIER board would cause a smaller shift to the actual received frequency (30-50Hz). This is indeed the way my radio is behaving. However, a 700Hz shift from the transmitted carrier frequency is required to hear a beat tone for CW operation. The circuit by means of diode switching circuit it inserts a 22pF cap in series to move the xtals frequency by 700Hz. However, using a general coverage receiver, it looks like it is only shifting 300Hz. I plan on purchasing a frequency counter to verify this.

If the frequency shift is 700Hz at the LO, should not the frequency shift be the same for the actual received frequency? Again subject to verification by the freq. counter, but there is definitely something wrong because I can't get the CW signal through the right position in the passband no matter how I adjust TC1. If I am confused or wrong please help me out.

Thanks,
Chris KQ6UP

21000. TS820 readout

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-20 20:27:01 UTC
From: Harlan
Topic: 21000 Message: 21000

I inherited the '820, and has performed rather good. Now, when I turn it on, it sometimes goes into a scan mode, and it does change the freq's when it does it.
Sometimes it only scans a few MC, and then maybe will scan a longer amount. I used to just shut it down, and restart, and it was OK. Now the numbers on the readout, make no sense at all and not all of them are displayed. They do react with the VFO tuner, but not correctly.

From: Tate Antrim
Topic: 21001 Message: 21001

I just recently picked up an AT-200. It seems fine but the SWR graphics of the meter are a very, very light orange/yellow. Shouldn't this be red? As such I can hardly see it. If anyone has a spare AT-200 (AT-230 I think shares the same meter) meter and would be willing to part with it please let me know. I checked with a few folks and none have this meter anywhere. I would like to exchange it out for one I can see.

Thanks

This happens a lot with older equipment that have been exposed to sunlight. Take a look at any HP gear with meters, the red seems to fade in some cases to nothing.

You can try to make your own meter scale using your PC. with the following software.

Mine is the same light orange so it's as is or it's aged the same.

The meter needle sticks on mine just enough to be annoying. Has anyone got a fix for this.

Hello Gene,

International Crystals in Oklahoma City, Oklahoma is another source for crystals.

http://www.icmfg.com/hamradio-manufacturers.html

Typical price is $21.95 plus shipping. Jans Crystals or International Crystals do not have "off the shelf" ready made crystals for Kenwood Hybrids. Both companies will have to make the crystal first then ship it to you. This usually takes about 3 weeks to receive the crystal.

Make sure you read and fully understand the FIXED CHANNEL OPERATION section in the radio's manual before ordering the crystal. Use the formula provided in the manual to determine the crystal frequency required for your specific frequency operation.

A fixed channel crystal provides one of the following options ONLY:

1. VFO receive, crystal control transmit
2. Crystal control receive, VFO controlled transmit
3. Crystal control transmit and receive, no VFO operation.

Remember, the fixed channel crystal options will not allow a non-WARC band Kenwood hybrid such as the TS-520 or TS-820 (all versions), to operate on any of the WARC bands, or any other band that is not selectable through the band switch. The FIX CHANNEL feature "replaces" the VFO and provides one of the 3 features listed above depending on what position the FUNCTION switch is set to.

The AUX band switch operation setting is not the same as FIX CHANNEL operation so don't confuse the two as being the same. The AUX band switch setting is for "receive only", no transmitting is available in AUX position. For further details on the AUX band switch setting, again, read the AUX operation section in the radio's manual.

Thanks mike. I am trying to locate an elmer with the proper test
gear. I am debating buying my own frequency counter. They are ~$100

for a decent one on ebay, but spectrum analyzers are $2000. I am also thinking of asking our club to have a fund raiser and purchase a full sweet of test gear.

I do agree with you on that xtal. It definitely behaves strangely. I was pouring over the schematic, and I can't for the life of me figure out why the received signal only changes very little when I change the carrier. I even studied out balanced modulator theory.

Amen to learning the rig. That is why I am not giving up on it. I believe it will help me understand rigs better in general -- especially boat anchors.

hey everyone, I'm Greg, studying for my license test and fixing up a TS-520s. I have a home made Carolina Windom Antenna I'm listening to you guys on and cant wait to say hi when I get my FCC ticket and can light up my tubes. This thread interests me and I thot I would stop lurking and give yall a shout out.

Ok, so I admit it, I am a gear whore, if it has a button on it I want to use it and even though I have acquired a vfo and dont really need fixed channel, I hate to have empty crystal sockets and a perfectly good knob that dosent do nothing when I turn it.

Aggh! it makes me twitch, ok sorry. I'm good.

Could some of you suggest a list of some good, neat, useful or just marginally interesting crystal freq to final frequencies that could put these sockets to use? I live in the southeast if that matters and would be interested in your suggestions. That would be way better than just me picking some random freq's to waste money on.

Thanks for your suggestions
Greg

My TS-520 has been modified by the previous owner to use the FIX CH knob
to select different CW filter widths. Far more useful...

Hi,
Just curious about something. There are no extra crystals in my radio. Is the display supposed to have any frequency on it when the "fix" button is pushed? When I first got my ts 830s it did not. After doing work on the PLL board it reads 6.500 when I push in the "Fix" button. Did I inadvertently repair something that should have been there to begin with or should the display indeed display NO frequency unless there is a crystal onboard?
Thank You.

Hi
I have not lighted the AT-230, but I did the AT-200. Uses the same brackets as the TS-520. It has the 2 cutouts for the little rubber bushings. I install 2 standard Kenwood pilot lights and ran 13.8vdc to the lights. It took some time to get to the mounting spots but was well worth it. I bet the AT-230 is the same.

It's got the proper CW filter, but also a third-party board with a switchable audio filter (Wood & Douglas CWF-1). The filter has four stages giving five settings, but I think the narrowest is left disconnected.

Yes this is correct. I was able to get it there at first, but after
reading Ken's post, I tried to find the "sweet" spot on the IF filter.
Then, I tried to put it back and it would not go back.

> KJ4GXN
>
There are issues with the counter either as an add-on to the 820 or factory on the S model. On my 820S I occasionaly have to remove the plugs for the display and clean the contacts and reinstall the plug (sometimes its just work the plug a few times) and everything works fine. I believe there is actualy a service bullitin on the issue from Kenwood.

I added a regular 14v lamp with pigtails, and wired into the 12v ac line
going to the vfo. lights everytime the radio is on

maybe that can be done on yours

OK-Thanks Mike. I have some cleaner/lubricant spray, and will do the contacts and check the screws to see if all are "tight". Where would I find the service bulletin? I did download the service and operators manuals from online.

> Hi,
> Just curious about something. There are no extra crystals in my radio. Is the display supposed to have any frequency on it when the "fix" button is pushed? When I first got my ts 830s it did not. After doing work on the PLL board it reads 6.500 when I push in the "Fix" button. Did I inadvertently repair something that should have been there to begin with or should the display indeed display NO frequency unless there is a crystal onboard? Thank You.
>

After more playing around, when pushing in the "Fix" button the frequency changes depending upon which band I am on. For example; on 80M it reads 3.000, 40M reads 6.500, so on and so forth. When the bandswitch is in the "Aux" position and the "Fix" button is pushed in the frequency reads .500. Just wondering if this is all normal? As I posted earlier the radio's display would not display anything before I "diddle-fritzed" with the PLL board.

21022. Re: TX Audio Super Distorted

From: Christopher Maness
Topic: 20941 Message: 21022

Ok, I did some more testing to try to nail down the distorted TX issue. The MIC gain pot and all connections are fine (checked with a DVM). However, I used headphones on my monitoring receiver, and I noticed at real low settings (no ALC deflection) I did not have much distortion. If raise the mic gain to about 7 or 8 and speek loudly the ALC would begin to pump (but not excessively) and the TX would get really distorted. If I turned the MIC gain down really fast the distortion would remain for about 5 seconds and slowly fade back to normal. This was with out the speech processor on. It was acting like a compressor with a really long recovery time. That didn't seem normal. Maybe a RC circuit gone out of whack some where.

OK, as far as the CARRIER pot. This seemed a little strange, but I don't have a working rig to compare it to. Even though it is a 10k pot, I only measured 75 Ohms across the left and right leads. If I measure between ground and the center lead I get:

1 = 0 Ohms
2 = 1k
3.5 = 2k
5= 2k
6=2k
7=1k
10=75 Ohms

I was expecting 10k not 75 Ohms across the L/R leads, but I guess that could be other components in the circuit causing this. Again, I don't have a working radio to compare its behavior to.

Thanks,
Chris KQ6UP

Gordon
Can you post a copy of the schematics of how you wired the filters in or send me a copy? I will go over the schematics I have and see if I can switch out the 2.1 to 2.8 SSb filter. I have the 500 hz CW filter that works great. I could not be more pleased. But on SSb I have changed out the SSb filters twice and depending on the conditions. I hate to mod the radio but, I might consider a swith on the back to switch out SSb filters, or use CH 3 and 4.

A common problem if the rig has not been used for a while.
If the tuned frequency jumps when the display jumps, it's the VFO variable cap ground wiper.
Open the hatch on the VFO can and lightly apply Deoxit to the wiper then spin the dial a few
times.
Repeat until stable. Don't overdo the Deoxit.
See Gordon's excellent photo's for guidance.

Hello Greg,

I recommend you listen on all bands, within the frequency allocation based on "your" class of license, at various times of day. This will give you an idea of what topics of discussion and any nets you may be interested in becoming involved with. We can't tell you what's best for "you", only you can determine that. Listen around on various bands to get a feel of what's out there.

Good luck with the exam.

One more thing Greg.

At this point, I do not recommend you spend money on crystals for the FIX CH options. It would be a huge waste of money. I recommend waiting and "if" you join a net or group that is always on a certain frequency and you join that group, then it would be logical to order a crystal. Although FIX CH crystal control sounds "neat" or "cool", it does have it's limitations and you should be aware of those limitation before spending money on crystals.

Of course, it's up to you whether or not you spend money on crystals but I don't recommend it at this stage.

21031. TS-830S Power Transformer Secondary Winding No-Load Voltages?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-23 02:12:18 UTC
From: oldamateuradioman
Topic: 21031 Message: 21031

This one of those moments that something I should know from experience just escapes me. I'm finding that getting older has it's disadvantages sometimes.

My question is in regards to the "no-load" secondary winding voltages on the power transformer of my TS-830S transceiver.

From studying the schematic, it is LABELED that it has a 800/400/0 winding and a 300/210/100/0 winding for the high/medium voltage supplies to the rectifier board.

QUESTION: With these wires completely disconnected from the rectifier board, what "actual" voltages should I expect to see when measuring each winding tap with a suitable voltmeter?

In some quick voltage checks with my Fluke DMM (and with a Simpson 260) I not reading anywhere close to the voltages indicated on the schematic drawing LABELS.

At each winding tap, no-load voltages aren't even half of what's indicated on the schematic and rectifier board markings.

Perhaps these schematic & rectifier board LABEL MARKINGS are not intended to indicate actual no-load secondary voltages but are just reference points for proper wire connections?

Here's hoping some of you will be willing to end my confusion with some advice. It's most likely a simple concept, but for now, it doesn't make much sense.

Tnx & 73, Bill, w0ng

Not necessarily Chris.
side band inversion takes place when the mix product is the difference
between LO and signal.
the easiest illustration is think of a 5 MHz VFO and a 9 MHz IF
20mtrs USB and 80mtrs LSB. As long as you carrier xstal is at 8.9985 MHz

Is this the case with the TS-520S? I am looking at the CARRIER board theory of operation in the manual, and it states that it shifts the CARRIER _up_ in the passband of the Xtal filter when in USB mode. That would seem to indicate that the LSB would be "visible" in "window" of the xtal filter if the carrier was at the top of the passband. Am I correct?

Hi,

Had an issue with an 820s display that was not stable. Cured the problem by re-flowing all the feed thru connections on the two boards in the counter assy. module. There are a number feed thru's on the boards, but not a difficult job.
I wicked each one of the feed thru connections, and then re-flowed them.
Worked for me!

From: Jeramy Ross
Topic: 21000 Message: 21040

In addition to re-flowing the solder on all of the feed-thru connections, I have found that some have TC-1 on the IF board adjusted to a point where the counter is not getting a strong enough signal. I could have sworn that there was a bulletin put out by Kenwood saying that the level to shoot for (0.1V) listed in the service manual when adjusting TC-1 on the IF board was in error, but I can't for the life of me find that anywhere in my documents.

Best,
Jeramy / W5XTL

I doubt there is a bigger idiot than myself.alas.I have an original AT-200 manual and spent who knows how much time looking at the schematic and there in solid black and white is the info about the diodes I was looking for.

I'll slink away and not bother to come back for at least a fortnight.

21043. TS-820 Final 470 uH choke coil toasted

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-24 03:28:55 UTC
From: chris_yipyap_com
Topic: 21043 Message: 21043

Hi group.

With your persistent help I have my TS-820 actually putting out a signal these days.

But today it started smoking and the power level went down. So I opened it up yet again and looked things over. The choke coil in the final section is toasted. I believe it is the one marked L4 in the big schematic. It goes between a 10k 1 watt resistor and a ground point near the relay and it consists of two windings on a form about 1/4 inch in diameter.

I see from past posts in this group that I can probably find another one. But before I do that I wonder if this is a symptom of something else that needs fixed?

Topic: 21041 Message: 21044

Bob,

The 830 and 811H manuals both provide the necessary information to make the connections you are considering.

If you do not have the 830 opoerators' manual you can download it free at the following website:

http://www.kenwoodusa.com/Support/AMA_Radios/#_

If you do not have the AL-811H manual you can download it, also free, at the following website:

http://www.ameritron.com/Product.php?productid=AL-811H

Page 5 in the 811H manual shows, with a drawing, how the ALC and 811H internal T/R relay connections to the transmitter/transceiver are made.

Page 13 and 25 in the 830 manual discusses/shows, with the remote din plug pin assignments and a connection picture, the 7 pin din socket connections for ALC and the "Normally Open" amplifier relay connections. The ALC ground return is the din plug's outer metal shield.

Use shielded cable in both relay and ALC connections between the amplifier and the transceiver. Simple stereo interconnecting cables are quite acceptable to make those connections. You will have to wire the cables to a 7 pin din plug in order to make the connections, T/R relay and ALC, to the TS-830S. Once this is done, label each cable's purpose/use, "Relay" and "ALC".

There is no need for an external amplifier relay control circuit/box between the 830 and the AL-811H. The 830's internal relay contacts are more than capable of handling the AL-811H's low DC (12VDC) relay control voltage.

I recommend reading and fully understanding the connectin, operating, and tuning information provided in both manuals before attempting to connect and operate any linear amplifier with your TS-830. If you have never used a linear amplifier before then might I suggest you enlist the help of a local ham who has experience tuning and operating an amplifier with a transceiver, to help you.

Failure to follow the information provided in both manuals can result in damage to and/or improper operation of both pieces of equipment.

Replying to myself...

It seems to me if this choke toasted it is because I've got some
DC on my antenna line. The blocking capacitor is supposed to keep that from happening. So I probably have a leaky blocking capacitor.

It does look a little bit off color. The schematic says it is .001 at 3KV. I will see if I can come up with one of those.

What do you all think about this 470 uH choke? Is that a precise value or will something larger/smaller do? I will have to research a bit to see if I can find one. I do have something similar but it looks like a higher value. I could wind one on some toroids that I have on hand.

Chris

You are right Troy,
I missed that. Sorry!
I found some here that might work but if not, I'll order a few from the partstore.
Thanks .

73,
Gordon

21060. TS-830 Band switch

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-24 21:19:05 UTC
From: waterfield55
Topic: 21060 Message: 21060

I was switching bands and my band switch coupler broke almost in two. I have a new coupler on order from Ken, how ever the shafts are not in alignment. I am thinking I can just match up the marks on the shafts created by the set screws. Am I on the right track?

From: Lou Blasco
Topic: 21043 Message: 21063

Hi Chris,

From my reading of the circuit that choke is in the screens supply.
There are notes in the circuit indicating typical voltages during
transmit and receive. Are they correct for your set? You say " ...
some DC voltage on my antenna line". How much? Where is it coming from?

I just did a search and Pinnical Mirco has them. You can get a replacement in another package if you want. I bet if I did a larger search you could get an exact HP replacement. Quite a few suppliers carry small amounts of these parts but they are not published. You will find one. Gene

21066. For Sale TS 830S Gold Edition

Yahoo group: TS-520_820_530_830 (2009)

From: paulch1956
Topic: 21066 Message: 21066

I have for sale a clean, working condition Kenwood TS 830S Gold Edition transceiver. The face plate is clean and the case has no scratches, dents or dings. It came to me with an SSB filter but no CW filters. Loads to 100 watts. New finals installed early 2009. The rig is in need of alignment. Also included a very nice MC-50 Desk microphone and an SP-520 speaker. Asking $450.00 for package. Will split shipping costs with buyer. Email if you would like to review some photos of all included.

From: waterfield55
Topic: 21060 Message: 21067

I read through some of the other post on here.
If I am understanding correctly:
As viewed from the front, I have the rig on it's side. The opening into the final cage is at the top. The flat of the rear(shortest shaft) should be facing up (band switch set to 10 or 30M).
If I use this for an alignment point, the flat on the short shaft is up (facing to the right side of the rig if it were in the normal position) and the other set screw point is facing down (towards the bottom of the rig.
When my shaft coupler arrives, I am going to take pictures and post them. I see I am not the only one who has suffered this fate.

The AL-811H will work just fine with the TS-830. Again, no external amplifier T/R interface between the 830 and the AL-811H is required. Simply follow the instructions in both manuals and you will do fine.

From: jimmyz2k
Topic: 21072 Message: 21072

Hello all,
It has been a long time since my last post here.Finally made it to General class and now thinking of connecting this Heathkit SB200 to my TS520SE.From what I found online,most people are using a Softkey modification on the SB200.This from what I read is for later model transceivers.What I still do not understand is,does this allow the amp to be used without the special cables?I will not attempt to operate his unit until I find more details on using it on my own radio.Anyone that has specific details that would help me would be appreciated.I do also know that it may need some part replacements due to age.It is in fantastic condition however and I would like to see if it has an output before I spend time and money into it first.Thank you.

Date: 2009-04-27 03:19:38 UTC
From: blacklabpupp
Topic: 21073 Message: 21073

I have always used a solid state rig for CW until I was given these TS 820's. I have been using a straight key with one until I picked up a CW keyer at the fest. Can you use a keyer straight into the outlet for the straight key or do I need to build some type of keying device for the grid block keying? I dont think the keyer is going to be able to do this on it own. Gene

21074. ts 520/ 520 acces to driver tube socket?

Gene,

You didn't say which keyer you bought. Most, if not all, CW keyers can easily key the 820's low CW keying voltage. I use an MFJ-407D but have used other solid state CW keyers with my 820 without any trouble.

I need some advise on the size of grounding straps from the transceiver to the common buss bar that all the other equipment is going to be grounded to. And what about a strap from the bar to the window pass-through? Since I can't go very deep into the earth because I hit solid rock, should I have several ground rods connected together?
Let me know some of your grounding techniques. You do have them grounded of course!!!
thanks, group
Robert

i am not sure of this whole grounding subject.i suppose this opens a big can of worms but i have talked to other hams who have had everything grounded only to be hit by lightening. so,is this an attractive path to ground by lightening?i am not sure but i disconnect antennas and ac power and chassis grounds in bad weather.......mike

I need some advise on the size of grounding straps from the transceiver to
the common buss bar that all the other equipment is going to be grounded
to. And what about a strap from the bar to the window pass-through? Since
I can't go very deep into the earth because I hit solid rock, should I have
several ground rods connected together?
Let me know some of your grounding techniques. You do have them grounded of
course!!!
thanks, group
Robert

We get some very violent storms here in winter. It's good to be able to disconnect your antennas way outside the shack in bad weather and don't ground them because it'll just make them more attractive to the lightening. If your antennas hit by lightening you don't want the lightening to go to ground in the house.
Our house is built on limestone bedrock and we have very little soil and it gets very dry in the summer. I've got a single earth rod into the rock as an RF earth and I only use dipoles or spinoffs of dipoles so the RF earth isn't that important. Everything works fine and I get good reports, the neighbours don't complain and the safety earth comes courtesy of the electric company.

Robert;
Old rule of thumb for ground, the larger the conductor the better, so if you have 3/8 inch ground strap, good - if you have 1/2 inch ground strap then that is better.

If you have a building ground, normally located outside the house where the power company meter is or outside the house near the breaker panel, you should tie any additional ground rods to that using at least #6 AWG copper. If you have a problem getting ground rod into the earth, you can also bury un-insulated (Bare) copper wire in several directions and tie that also to the building ground and use that for the shack. I have run these types in VA where I used to live, four bare #12AWG each around 100 feet in length buried about 8 inches deep. This gave me an excellent ground.

Also, during violent storms with a lot of lightning, it is better to completely disconnect antennas if at all possible and get conductor out of the shack. Additionally, if you have very high wind and long radiators in the air, watch for high static electric build up on wire antennas that are connected to your gear (I had a full size 160 meter dipole with twin lead feeder that could arc to ground in high wind storms, and really get your attention).

Hope some of this helps.

Regards

Chuck, KJ4GU

21084. Re: Grounding

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-28 19:35:23 UTC
From: Adam Wade
Topic: 13210 Message: 21084

First off, you want to make sure that any AC or high voltage goes to ground and not through you or other equipment. Second, you want to make sure you don't have multiple paths to ground of different lengths, which creates ground loops which bring noise into your gear. And lastly, there is the lightning protection issue.

On the first two, assuming you use coax to connect all your gear together (and just about everyone today does), you already HAVE a ground system tying everything together -- the braid on your coax. Adding an additional ground will give the potential that AC won't be carried on the coax braid (but since the coax braid has very lowimpedance at 60 hz, a bunch of it will travel on the braid even WITH an expensive grounding system). However, it will almost certainly create the potential for ground loops, and possibly even worse, if you have any common mode current on your coax, you could all all sorts of weird signal strength dips based on resonances interacting between your different grounds! I've had this happen to me with a vertical, where I had a station ground and another ground rod at the antenna tied into the radial field and coax braid. I could not get the antenna to tune properly, and had weird humps where the SWR should have been low from tuning
the antenna to resonance. I disconnected the ground rod at the feed point of the antenna and all the weirdness went away and the antenna "behaved". The station ground was about 50 feet from the antenna ground, and I was giving some of the RF two out of phase paths back to the amp/transciever.
On the subject of lightning, nothing is going to prevent lightning from damaging your gear except unpligging it from any external wires at ALL, including removing the AC cord. A lightning strike even a mile away from you can produce surges in anything with an external wire attached to it, in many cases strong enough to kill the gear -- with or without a heavy duty grounding system.
In order to prevent lightning damage, you simply prevent the lightning. Have a look here, about halfway down the page. http://www.amfone.net/AMPX/114.html This guy has the ultimate solution to protecting his gear, and reading the article will help folks understand much better how ligtning forms and how to get rid of it as a threat to your equipment (here's a hint: The sky and ground form a huge air gap capacitor, and it's the discharge of the cap that is the lightning. How do you get rid of the charge in a capacitor without creating a huge BANG and an arc scar on the terminals? If you've worked with tube PAs before, you probably know the answer already, but the article shows you how to make an analog for lightning of the answer you probably already know...)

The silver top of the mike un-screws. The connector on the bottom likewise unscrews. The threads often have a glue like substance on them like loc-tite.

Use a hair dryer to heat the threaded part and soften the glue. If the element is damaged, get back with us and we will give you some replacement ideas.

Date: 2009-04-29 01:14:26 UTC
From: James French
Topic: 8317 Message: 21087

Hello everyone.

Name here is James and the call is W8ISS.

I was given a ts-520s a few years ago and finally getting around to seeing if it actually works or not. This is my first HF radio that is a hybrid type. All other HF radios I have used have been solid state as in NO tubes.

I joined the group to troll through the previous emails and to ask questions about the proper operation of this type of radio. I have been getting advice from a local about this radio and it has been helpful so far.

I have run into one stumbling block though. The radio seems to be working for receive, but I have not yet picked up a signal yet. I am getting sound out of the external speaker jack and the 25khz reference seems to be working but a little off. All I am using right now for receive is a vertical about 15 feet off the ground. I haven't even tried to transmit with this yet so I have no idea if that works yet. I have picked up plenty of signals with other receivers across the bands. Any suggestions?

James W8ISS

21088. TS-820S question

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-29 04:02:35 UTC
From: Gordon
Topic: 21088 Message: 21088

I am aligning a TS-820S I have here on the bench. When setting up the Carrier frequencies to 8831.500 and 8828.500, I notice that the background noise is VERY different between USB and LSB. If I alter the USB so that it sounds as good as the LSB, then my CW offset is way off from where it should be.
The other 820 I have doesn't have this kind of difference.
Has anyone run into this and if so, what did you do to cure it?

Thanks,
Gordon

Walt I have a couple of MC 50's that need mew elements. One was bad the day it was purchased and never returned, the other just quit working after I loaned it out. I think the element is bad in both, one I am sure of and the other maybe. What do you recommend for a change out the sounds as good as the MC 50? These mic's may not sound well on other radios but on TS 820 it is hard to beat.

Mike
I have two keyers now. The one I think I am going to use is a MFJ-481. The other is a kit about 1x2 and it has no name on it. It might be a pixie, not sure, maybe pic keyer from old. I need to download a manual for the MFJ, because I am not sure if I can safely use the direct or grid block socket on the rear. Any advice? Gene

> Any suggestions?

Without knowing how big the vertical actually is, it's probably hard to say if it would be suitable for transmitting - probably not. The valve PA in the TS-520 family is pretty robust, and will match some really quite bad aerials, but it's got to be at least *approximately* right ;-)

You say the 25kHz reference is off - it's probably just that the dial is misaligned. There's a whole procedure in the manual for calibrating the VFO and reference oscillator, which may be worth following at some stage (I did it and my main dial is still about 18kHz out, ie. when set to 0 the line is closer to 25. I suspect the dial has moved on the shaft, everything else is bob on).

You don't say if you have a manual, so if you don't have a quick google and you'll find a nice archive of them provided by one of the helpful and generous members of this list. If you haven't used a hybrid rig before, you'll need it. Setting up the final isn't difficult but does require things to be done properly and in the right order, otherwise you're buying new valves (and these days, new cathode resistors too).

Okay, why might you not be receiving any signals? Well, your aerial might be crap. Your earth might be crap. Your radio might be broken. Finally, you might be Doing It Wrong.

Let's check the receiver over first. Make sure there's a plug in the "EXT VFO" socket - that has a jumper that supplies power to the VFO and without that you will hear *nothing*. The fact that you can tune past the marker every 25kHz suggests that this bit is okay. Now, we'll set some basic settings just to check it all out. The meter reads signal strength in receive, so ignore the meter switch for now. The switches should be
Standby: REC
H. SW.: Off
VOX: Off
NR: Off
AGC: Slow

RF Att: Off
RIT: Off
Function: VFO
Band and Mode: as appropriate, let's use 7MHz and LSB for now
RF gain: all the way up
AF gain: as loud as you like

Okay, got that? If you tune around the bottom half of 7MHz you should hear lots of CW, PSK31 up around 7.035-7.080, RTTY above that and the maybe some phone. Tune the Drive control to peak the receiver - this not only tunes the drive to the PA, but the RX preselector. If you switch bands, remember to switch mode (USB/LSB) as appropriate, and look up the bandplans to see where you can expect to find stuff.

No good? Let's look at the aerial.

For receiving, a long-wire antenna will get the job done. Get a long bit of wire, tie one end to something high, feed the other end in through your window (leave a drip loop!) and connect it to the centre pin of your aerial connector. You'll need an earth of some sort, but how you go about that depends a lot on how your house is wired. Since my house is fairly recent (<50 years) in the UK, I have PME wiring which has its own peculiar set of problems. You could use a dipole and not worry about earthing (at least for receive).

If you've got this far, you have basically got your radio set up in a way that should receive *something*. If you still can't hear anything, it's possible that it's just not a happy radio, and you'll need to get involved with the insides.

Hope this helps,
Gordon MM3YEQ

The smaller keyer sounds like it might be the N0XAS pico keyer (a great little unit) mine has been happily keying my 830 for five years now.

Topic: 21093 Message: 21093

Hi guys, I've searched the forum and have seen this question asked, but never really saw a response. So here goes.

I've installed 455khz and 9mhz 500hz filters, I then aligned the rig per the service manual, then went back with a soundcard spectrum analyzer (glfer) and aligned the vbt osc. I now have a perfect 500hz window centered at 800hz. When I turn the VBT control counterclockwise, the filter narrows to abt 50hz (still centered on 800hz) within a few clicks... is this normal?

Btw the soundcard analyzer is pretty cool, you can see the effects of the notch filter, if shift, vbt, etc. as real signals come in.

73 Mark.

James,if you have access to a antenna anylizer it will generate a signal with tone.you can test this by listening with one of your other solid state receivers.this might give you some idea if it is working or not.hope this helps.Mike KE5GBC

Hello everyone.

Name here is James and the call is W8ISS.

I was given a ts-520s a few years ago and finally getting around to seeing if it actually works or not. This is my first HF radio that is a hybrid type. All other HF radios I have used have been solid state as in NO tubes.

I joined the group to troll through the previous emails and to ask questions about the proper operation of this type of radio. I have been getting advice from a local about this radio and it has been helpful so far.

I have run into one stumbling block though. The radio seems to be working for receive, but I have not yet picked up a signal yet. I am getting sound out of the external speaker jack and the 25khz reference seems to be working but a little off. All I am using right now for receive is a vertical about 15 feet off the ground. I haven't even tried to transmit with this yet so I have no idea if that works yet. I have picked up plenty of signals with other receivers across the bands.
Any suggestions?

James W8ISS

Gene,

The 481's grid block negative keying option is rated at 300VDC at 10ma. The 481's direct, or cathode, keying option is rated at 300VDC at 100ma.

The 820 CW mode's keying voltage, at the CW socket on the rear, is -1VDC at 1ma. Therefore, the 481's grid block keying option will safely key the 820 just fine.

Can you use a keyer straight into the outlet for the straight key or do I need to build some type of keying device for the grid block keying? I dont think the keyer is going to be able to do this on it own. Gene

Bill, I have found the same thing when measuring the voltages at the secondary taps of the transformer. The 800 volts connection, which is less than half of that, goes to the voltage doubler. My no-load HV plate voltage measures 947 volts, which had me concerned, but from other posts in this forum, it is apparently normal.

21098. TS830s Bandswitch problems and 2 tips

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-29 18:03:47 UTC
From: Steve Cooke
Topic: 21098 Message: 21098

Hi all,
In an attempt to fix intermittent loss of ALC on some bands on my otherwise excellent 830s , I've managed to lose it completely on ALL bands !!! I think I have found the cause , but stumbled across a couple of tips that I thought I would pass on in the meantime .
I removed the RF board to gain access to the rearmost wafer of the bandswitch , and found that a previous " repair " had been done to the fixed contacts . They had been squeezed together in an attempt to get a better contact with the wiper.
Sadly they had been squeezed too far - with the result that instead of the wiper going in between the contacts , it went over the top. The contacts were also loose on the board , the rivets were not holding them tight - I had to solder the contacts to the copper tracks.
I put the RF board back expecting the ALC to behave properly - the result - no ALC at all - and the RX side had gone deaf to boot !
The RX fault turned out to be a dry joint on connector 5 on the RF board that carries the RIF signal .
Whilst chasing the ALC problem , I stumbled upon the fact that with the SG switch in the off position todisable the finals , if you put the meter
switch to HV and flip the send switch , you can read the final's HT voltage - normaly you can only read it whilst in transmit mode and not in idle , the meter returning to signal strength upon key up. Might help someone diagnose impending HV power supply problems in the future .

They run anywhere from $400 to $675 (gold edition) on ebay. You can occasionally find a deal here or some of the ham classifieds for $300-$400, but they normally do not last long.

Good Luck,
Chuck

Gordan;
If you are feeling handy, you could build yourself a precision voltage reference. I made one some time back and use it to verify the accuracy of my DMMs. Take a look a the link below for some ideas, Maxim and Linear Tech used to make these ICs.
http://datasheets.maxim-ic.com/en/ds/REF01-REF02.pdf

21105. Operating at or near QRP with a TS-520S - How to

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-04-29 21:04:15 UTC
From: Jim Larsen
Topic: 21105 Message: 21105

I need a bit of help here. I am out of touch with how to use a TS-520S and I received a question from a ham who read a comment on my website about reducing power for QRP. http://www.al7fs.us/AL7FS1.html "QRP Getting Started"

Subject: Kenwood power reduction
Date: Tue, 28 Apr 2009 19:53:21 -0700
From: Steve <Yioutta@...>
Hi Jim
I was looking over your web page and noticed that you said you can
reduce power on the Kenwood. I have a Kenwood TS520s. I always tuned it for max power, thinking it would be out of tune if I did not. How do I reduce power without burning it up?
Thanks steve N7LWF

Can one of you provide a "how to" on reducing power to the minimum on a TS-520S while still keeping it properly peaked and dipped? Also, concerning ALC, is there a safe way to use N4BP's circuit from http://www.qsl.net/n4bp/alc_adj.jpg ?

Thanks for any help on this one.

That circuit looks pretty reasonable. You might also use the one about
2/3 of the way down this page:
http://www.radiomods.co.nz/kenwood/kenwoodts520.html

The hard and fast rule I was told at work was to forget the last digit. Digital meters from certain manufactors are plenty accurate. Not all are, but, I do have mine sent back for calibration every coulple of years. That depends on how much a day you use your equipment. Mine gets hard use daily, but if you use one once a week I doubt you would need to adjust it as often. As the rep told the boss dont waste your money on cheaper meters. You will never regret money spent on good test gear.

Hello all...

Name here is Rick and I am a new HAM as of 11-08.
I picked up a 520S as my first HF rig around mid February and have been enjoying it very much...even the "learning curve" hi hi

I have a small problem that I hope some of you guys may be able to steer me through.
The rig seems to work fine in every respect with the exception of 40 meters...the noise floor keeps the meter "pegged" and I cannot seem to receive anything...or at least can't hear it for the noise.

Just a few notes of "FYI" type stuff....

Station ground system is 3/16 copper (like used on "power poles") which runs from the ground rod at the power meter to a ground rod at the load center to a 3rd ground rod just outside the shack then up through the floor...a 4' piece of 12g wire is soldered to that and runs over to the rig....total run from meter ground to shack is about 30'...all wire is sold copper, not stranded.

I am using an LDG AT-100Pro ATU with all 3 antennas...

First, I put up an OCF dipole (4:1 balun at feedpoint) at about 35'...this combination works marginally on 80m and does much better on 20m (I've logged SSB QSOs in Spain, France and South America on 20m)

Next, I built a "standard" dipole cut for 1.900 up about 35'...this antenna works well on 160 and 80 meters...better on 80 than the OCFD...barely hear signals on 20m (which I expected)

Next, I built a fan dipole for 40m and 20m...again at about 35'.
This antenna was about useless :(

I have since put the OCFD back up since it works best for me on 20...none of them changed 40m.

I'm beginning to think it's not JUST the antenna...hi hi

Sorry about being long winded...any help greatly appreciated...

From another new member...

Put the rig on a dummy load and see what happens. If the noise on 40 goes away, it's coming down the antenna lead, if noise level stays high with no antenna and a dummy load connected, the noise is being generated in the transceiver somewhere and might be nothing more than an alignment problem.

At one time the "trick" to tuning RX's was to "peak" the noise by turning all the slugs in all the cans for max noise. Worked good on simple superhet designs using vacuum tubes and a couple of bands but with the newer double or triple conversion multi-band rigs, that method isn't likely to get the rig working to best advantage. Your rig might have been "Peaked" this way before you picked it up.

Good luck!

Ken - KB7H

21114. Bulb Replacement TS-520

Yahoo group: TS-520_820_530_830 (2009)

The bulb that lights the frequency dial is out in one of my TS-520s. Is it difficult to replace? Can I use a 12V bulb from an auto parts or radio shack store?

I don't have a service manual although I presume one is available online.

Thanks for the info.

Hi Joe,

Go to www.k4eaa.com for replacement bulbs at a good price.

Hello all,
I have been reconditioning a 520SE, and I noticed some arcing under the driver tube socket. It looks like a tough job to get access to the socket. Can anyone suggest a best method for getting access to the bottom of this socket?
Thanks and 73

If I remember correctly, Kenwood sold those lamps in the past. I ordered about 2 dozen of them some time ago. They are grain-O-wheat lamps, with about 4-6" leads on them. Not to hard to replace. I have also used the sensor lamps used in VCR repair, but they may no longer be available, since we live in a throw away world now.

But do a search for Kenwood East and ask them if they still sell the right ones.

Hi Rick. As Ken - KB7H pointed out, see if the noise is coming through the antenna or not. If its not, you may have a problem with the radio. Can you hear the calibrator on 40 meters? You may ned to do an alignment. The basic alignment of the TS-520S is not hard to do. The procedure is in the manual. If the noise is coming in via an antenna, you may need to try to figure out if something in your residence is causing it. Basically start unplugging all of your home electronics one thing at a time, and see if the noise goes away. Many electronic items can cause radio interference. One of the main causes these days is the cheap plug-in power supplies (also known as wall warts) used for cell phones and other items.

Let us know what you figure out.

TTYL and good luck.

You can go the this URL and download the manual for the TS-520

http://gmcotton.com/Ham_Radio/Kenwood%20Manuals/Kenwood-TRIO_TS520%20HF%20Trancievер_Manual.pdf

I have it on my system, and it's not a bad copy. Matter of fact, I have to
use it this week, as a fellow shipped one in for service.

Hope this helps you find all you problems.

Hello Joe,

No, auto lamps will not work as replacement lamps in your TS-520.

Although there are sections in the TS-520's operator's manual that contain maintenance adjustments etc, the TS-520's service manual should be consulted when servicing your TS-520. The service manual is available for downloading, free of charge, from various Internet website sites such as N6WK (http://www.n6wk.com/kenwood/).

Radio Shack sells a small 12V lamps that will work quite well as replacements for the dial and meter lamps. Radio Shack's part number is "272-1141" at $1.49 each, plus tax. If your local Radio Shack stores does not have them in stock then Radio Shack can order them for you and have them shipped directly to your house. I recently ordered 6 of them and had them shipped directly to my house.

Ken, K4EAA, also sells replacement dial and meter lamps, as well as other hard to find replacement parts, which are similar to Radio Shack's lamps.

The choice is yours to make. However, which ever choice you make, if your repair skills are limited, I recommend you enlist the help of a local ham who has repair experience.

21121. TS830S Tune Up Question

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-01 10:43:01 UTC
From: rdmegargle
Topic: 21121 Message: 21121

I have recently acquired a TS-830S and need an opinion on the best tune-up procedure. Reading the manual, it lists two: the dip/peak method or using the RF position--adjusting load and plate for max relative RF output.

Any opinions on the "best" procedure for this rig, or are they both valid? I've run nothing but tube finals for the past 33 years, but this is my first Kenwood and would like to have the experts weigh in.
Russ K8AF

Hello Russ,

I never bother with the R/F output meter, I usually load it to around 230 - 240 milliamps, there's no benefit to going higher, but it's important to ensure that you're registering some ALC voltage when you do this.

If you're planning to use CW then, after tuning, back off the CAR control until the ALC no longer indicates, you get a lovely clean CW shape that way.

Remember if you're using an external tuner for whatever reason (balanced feedline etc) to tune your TS-830S as above into a 50 ohm dummy load first, then switch in your tuner/antenna and adjust your tuner to match.

That's all there is to it.

Hi Russ,

I use the dip/peak method just because I want to get the plate current down ASAP, and at the same time I watch my antenna tuner watt meter to see max. output. Just my preference.

Hello All,

I believe my noise blank function may not be working properly. If it function somewhat like the NB on my 857D I would expect it to cut out electrical noise, some forms of RFI etc, or at least reduce it by x amount.I have tried flipping the switch on and off numerous times. Different bands, different forms of rfi etc with no noticeable reduction. My question, is this function not very noticeable on this unit or might I have an adjustment or circuit problem. I have been studying the schematic a little but wanted to get a little insight before removing the cover. Any help is appreciated.

Can you hear WVV that should come in where ever you are on a minimum antenna. Right now and for the past few years we have been in a sun spot minimum and DX is pretty dead on most bands.

Hi Jay,

First question from me is what kind of noise are you expecting to
reduce? The Kenwood noise blanker is very good at removing impulse
noise. It won't remove hash or continuous noise. I have an electric
fence about half a mile from my aerial and without the blanker it's
there all the time. With the blanker in, it's gone altogether. I
guess you can test yours by flicking your light switch on and off a few times.

Hello Lou,

The noise I was hoping for it to reduce was power line noise that tends to spike at times. I also have a lot of wireless routers in the neighborhood which I would like to quiet down if possible. I use the IF shift and the RF Gain with some success but I cannot tell a difference when switching the NB in and out. I did try switching different light switches on and off with the NB in different positions but could not tell a difference. Hope this help.

Thanks

JR

My Twins NB is very effective on impulse noise (ignition, weedeaters etc) -
at least as good as my TR-4CW/RIT blanker. I would not expect much efficacy
with uncorrelated power line noise from an impulse type blanker.

Dale W4OP

Hi Jay,

Depending on the type of PLI you have you 'may' get a little relief
from the NB but the wireless router interference is a lot more
difficult to eradicate. I had a D-Link router that would generate a
sound like water dripping into a bucket on HF. It sounded similar on
SSB and AM and ran all the way from 2MHz to about 25MHz. Only way I
could fix it was to turn off the router. Not a solution for you
unfortunately. I'd say your NB is probably OK but the noise you have
does not have a sharp rise time and hence goes straight through unaffected.

Hi Guys. While some routers may produce some RF, the most likely cause is the cheap, crappy, switching "wall wart" type power supplies that they come with. I had a bad noise problem that I though was my router...until i hooked it up to a non-switching supply. I now use the same router, but the noise problem is gone. Unfortunately, many electronic devices today use these type of cheap, crappy, Rf polluting power supplies. I believe that many of these power supplies are violating FCC rules, but there seems to be no interesr from the FCC in solving the problem.

I have seen cell phone chargers (motorola razors are the worst) that wipe out HF from below the AM broadcast band to over 30Mhz with S-8 to s9+40Db signals. This when the natenna was more than 100 feet away.

Fortunatley for me, I only have 2 close neighbors, and their stuff don't bother me RF wise (so far...keeping fingers and toes crossed!)

Anyway, the noise blanker on the older Kenwood radios were mainly meant to work on impulse noise, such as from a car ignition. They don't do much of anything for other types of noise.

About all that you can do is make sure that your own home electronics are not part of the noise problem.

21132. Filters For TS 820

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-02 10:15:56 UTC
From: blacklabpupp
Topic: 21132 Message: 21132

I am in need of two more SSB filters. Does anyone know if a YK 88s will work in an 820? It looks like I could wire it in but I am not sure about it since it came from a TS 440. I believe this filter is for 2.4k but I also need another for 2.8k. Can anyone give me the correct numbers to look for? All the filters I am currently using are INRAD and I refuse to purchase amy more from there. They are good but the price is just to high. I can do alot better at the area hamfests. Ok so call me cheap. Gene

I have a nice YK-88S filter (2.4 Kc bandpass & solder-in type)...
Pulled form a TS-530S that had a hot receiver...
Would take $45.00 plus $3.00 for postage...

The YK-88S1 is a 2.6 kc bandpass... (sold out)
The YK-88S2 is a 3.0 Kc bandpass... (no stock)
Not sure about a 2.8 Kc filter??

Forgot to add...
The TS-820 & 820S uses a YG-88S SSB filter...
It is larger & has different mounting solder terminals than the YK-88S filter from the TS-530S, 830S, 430S & 440S....

Thanks for the reply's. Unfortuneatly for me I am surrounded by at least 5 wireless routers. I did test mine and it is one of the culprits. I did find that it was not the power supply but the router itself. I have a SGC 239 coupler attached to 100' of wire which loves to attract RFI anyway. I was just hoping that I had an issue with the NB I could fix so I could expect a little more relief from the noise.

Is the SGC mounted outside with a good RF ground on it, and a decent ground isolation transformer inside the shack? If not the feedline will/can couple noises from the house out to the antenna in common mode, where they are picked up by the antenna and back to your rig in transmission line mode.

21137. HV Reading in Transmit on TS-520S

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-02 21:09:17 UTC
From: scott10k
Topic: 21137 Message: 21137

I was not getting an HV reading on the panel meter when in SEND mode. In this case the problem could be solved by tracing continuity and checking the voltage divider resistors on the HV Board. CAUTION-in a no-load condition, there are about 940 volts entering this board. Be sure to unplug the radio and discharge the HV capacitors and the capacitors on the rectifier board before testing the HV board.

One of the 680k voltage divider resistors had increased resistance to a very high value and another had an open connection. Replacing both of these resistors restored HV readings on the panel meter.

> SV0XBQ

Hi Chris,
I have been working on an HV problem on my TS-520S when I came across your query. Here is an eBay source for the HV filter caps, which I have replaced and am happy with the seller and the result.

http://cgi.ebay.com/Kenwood-TS-520-TS-530S-TS-820S-TS-830S-HV-Filter-Caps_W0QQitemZ130302928231QQihZ003QQcategoryZ4674QQssPageNameZWDVWQQrdZ1QQcmdZViewItem

Did you try to replace the driver tube? On my 520S the unloaded HV is 947 and the loaded is 800 volts, so you are pretty close. There will be variations from one voltmeter to the next.

The TS-520SE is not capable of producing 200 watts "output". If one is using a watt meter and the watt meter shows 200 watts output I seriously question the watt meter's accuracy.

Indeed. The power supply is only capable of putting out about
200W-worth of HT at best. If one can measure over about 100W RF output,
something is not long for this world.

Gordon

Keep an eye on eBay - they do crop up from time to time when people part out broken sets.

The send switch isn't a biggie - as long as you can switch it to receive, you can always just use the PTT line on the mike socket.

Hi guys...

Thanks for the input...I have found that the noise disappears when the antenna is disconnected and that I can hear the calibrator on all bands.
My next step will be to shut off the main breaker to the house and bring in an extension cord from my shop to power the rig (this would let me know if the source is something inside the house).
If I find that the noise is coming "from within", I'll start an item by item search.

Thanks again..

Hi Alex. How long had the radio been on before you started operating?
I do not think that the antenna relay would cause this sort of
problem. Possibly one or more parts in the low voltage supply are
going bad.

Good luck.

Search back through the list archives for advice on drifty VFOs. A few people have experienced this - I daren't say I haven't, because if I do mine will promptly start wobbling all over the band.

The first hit I got suggested replacing D5 and Q7 to cure a drifty TS-820. These correspond to Q4 and D3 on the FIX CH board in a TS-520, and provide a regulated 9V supply to the VFO. Check the supply from them to see if it's still anything like 9V, and see if it changes.

Thanks for the feed back on the switch I guess thats what I am going to have to do find another kenwood for parts I do see 2 on ebay in the u.s for parts, very rarly get to many here in vk,the good kenwoods are attracting good prices on ebay here ,nobody would pay anymore than 250-350 aussie dollars a couple of years ago good or bad,now your looking between $600-$1200 and possibly more and yes I would pay that for an 820s
So does bob k5ftf have an ebay or web site for these parts

I have just dealt with Bob KE5FTF . I found him on QTH.com swap section http://swap.qth.com/ . That is where he has listed the parts he is selling. You can email him as well from there .

Also Hello to the group .

I've seen this before. Frequency jumps when certain things change... abrupt small frequency changes etc., usually means the screws on the RF board worked loose and ground is getting shaky. Tighten down the screws that hold the RF board.

21154. Using an SB200 on a TS520SE

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-05 03:07:44 UTC
From: jimmyz2k
Topic: 21154 Message: 21154

I apologize if this is already posted.I feel I have searched everywhere and get vague results.I would like to use an SB200 amp with my TS520SE.I have found an old tube which the socket pins fit perfectly on the Kenwood remote socket.This will work great for the cable I want to make.I need to know what pins for ALC and Ant relay on the amp go to on the TS520SE.I have the manual for both units,but still I am confused.I do not want to fry anything.Any help here would be appreciated.

My 520 had that problem, it would jump as the rig warmed during the transmit cycle. Turned out that a screw was missing from the bottom of the VFO.

I inherited a TS-520S which hasn't been used for receiving in 15 years and transmitting in almost 20. I just got my Tech license so there are a few spots in HF land where I'm allowed to play with it (and more when I learn code)

I'm trying to get it tuned up on 10M with a homemade dipole and I'm noticing that when I set it to TUNE mode, It drops from 28.3xx to a stable frequency near 26.900 on my DG-5. I'm able to follow the tuning procedure from there, but I'm wondering whether something is broken.

Also, sometimes in SSB I see that the frequency is stable when I key the mic, but when I speak it sometimes has this same problem, though it's jumping all over the place.

Is this normal? If not, what is wrong?

thanks

21160. Swapping 6146 Finals on two TS-830s

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-05 19:37:59 UTC
From: ko6ww
Topic: 21160 Message: 21160

Hello Group,
I have two TS-830, one which seems to have been tempered (Chassis holes) and a second one unmolested. The first have the RCA 6146A which measure about 140W the second rig has the Sylvania 9146W which measure about 120W.

I want to swap them, but don't know if I need to neutralize them (Which I don't know how) before I proceed.

Any advice will be well taken.

Cheers,
KO6WW

If you change the output valves, you'll need to neutralise the PA. The procedure is documented in the manual. They're not kidding about needing a non-metallic screwdriver.

When I fitted PA valves to my TS-520 I used a metal screwdriver (with the set off, caps discharged, left hand in back pocket and girlfriend on first-aid standby) to loosen the very very stiff neutralising cap - 30-odd years of stiction and dry grease needed to be freed off! To actually neutralise the set, I used a "screwdriver" made from a hard acrylic knitting needle.

It sounds like both sets are pretty healthy as they are. To be quite honest, I'd be most inclined to leave them alone if they're working.

Gordon

If you are looking for the additonal 20W output, it will never be noticed on
the air. That difference is around 1/2 of a dB.
Should you decide to do the swap though, neutralization would be required,
unless you get very lucky.

if you don't have an rf probe or a scope to neutralize the finals, you can use another set tuned to the same frequency and just adjust the capacitor for the weakest signal heard.

Hi Jon,

The rules can be found in the files section but I've reproduced them here for you

Regards

Lou
VK3ALB

Rules pertaining to Occasional For Sale and Want to Buy Posts.

Members of the TS-520_820_530_830 Yahoo Group who have been members for at least 30 days may place offer for sale posts no more frequently than two in any 30 day period. Want to buy posts are permitted immediately upon membership and are limited to 2 in any 30 day period.

For sale posts may include sale of TS-510, 515, 520, 820, 530, 830, and the 599 series twins, as well as Kenwood accessories intended for use with these radios. Posts relating to non-Kenwood accessories commonly used with these radios may be posted, but please use discretion.

Posts must include the make and model of the item for sale as well as an accurate description of its condition and the asking price.

When the item is sold, please make a short post to that effect.

Replies and discussions regarding these posts must be taken off of this group either by direct e-mail to the seller or to the Kenwood QSO group as directed by the seller.

Buyers and sellers are on their own. The TS-520_820_530_830 Yahoo Group, its owners, moderators, or members other than the seller hold no responsibility for the accuracy of the posts or the credibility of the seller or buyer.

We do not expect that members of this group will misrepresent or in any way cheat other members. At the moderators discretion, we may choose to ban any member from making further for sale posts, or ban the member from this group entirely if we believe his posts or transactions are not of the utmost integrity.

We ask that those who buy and sell equipment as a main business not post here. We will allow posts from members who occasionally restore and sell equipment.

We expect our members to use discretion. If excessive traffic
develops as a direct result of these postings, they may have to be
discontinued.

Pin 5 to control the relay, pin 6 ALC. I would however strongly recommend a buffer such as the Ameritron ARB-704. They're only $60 and are good insurance. That's the way I am driving mine. I'm not driving it with the TS-520 at the moment, but I have in the past.

Good luck with it, and there is a great yahoo groups for Heathkit linears also. Lots of good info there on the SB-200.

From: Luis Estrella
Topic: 21160 Message: 21170

Kevin,
I have the SM-220 which can be used as a scope, although I only use it to monitor my voice.

The reason behind I want to swap the tubes is because the radio that have the RCA 6146A's is a radio I got on e-bay and its condition is not the greatest, it has been tempered. On the back panel there are extra holes which seems like there were switches installed at one point. My other radio is one that I had over ten years and is in very good condition, so I am just trying to bring it to its original state.
Neutralizing is something I would like to learn as I expect to keep my hybrid Kenwood radios as long as I maintain my interest in amateur radio (I been licensed since 1993) I search on YouTube hoping to find a video illustrating the process of neutralizing, but could not find one. If anyone knows of a good comprehensive step-by-step procedure please let me know.

Thanks,

Luis

if you don't have an rf probe or a scope to neutralize the finals, you can use another set tuned to the same frequency and just adjust the capacitor for the weakest signal heard.

Luis,
Here is the best discussion I have seen on how to neutralize the finals. As stated in the manual, be extremely cautious due to the high voltage, and use an insulated screwdriver to adjust the neutralization capacitor.

21173. Noise on receive (was: new member)

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-06 15:33:23 UTC
From: Ken Hunter
Topic: 64 Message: 21173

I might add that I've found that my wife's air cleaner/filter does emit RF radiation (mostly spectral noise) at certain parts of the bands. I notice this mainly on 20 meters and it can be "tuned through" IE. it is more prevalent on certain frequencies. I suspect that there is some RF "Hash" from an internal microprocessor.

I've also had an aquarium heater that gave me a "Buzzing sound" when the contacts were switching. This switching at times took 20-30 seconds to go from an open to a closed condition, all the while trashing the whole band. Don't forget the electric blanket controllers, anything with a thermostat, etc.

If your noise had been coming from the antenna, I'd suggest that you use bare wire rather than insulated, especially on a dipole. The nylon or similar insulation materials will generate quite a bit of static voltage as the wind blows. This static is discharged to the atmosphere from the ends of the antenna. This can be reduced somewhat if you terminate the end of the wire so that it is in a small loop (maybe 2 inch diameter) rather than a "pointed" end sticking out. Loop antennas, (those without a high impedance "end") are less prone to self generated noise.

Hope this helps.

Date: 2009-05-07 00:40:32 UTC
From: blacklabpupp
Topic: 21175 Message: 21175

I was asked tonight if it was necessary to move the plug on the bottom of the board when you install a CW filter. I cant remember if it is only to be moved if you use FSK or not. Does anyone know the answer right off. When useing a CW filter how far off is the dial when you use it. He told me after he installed the filter the center of the signal moved some. I have never noticed it becasue I never look at the freq I just tune up where I hear it. Gene

Gene,

Each model has wiring or plug changes that must/should be made
when installing a CW filter. These changes are fully discussed
in the individual model's operators manual. The dial settings for
the different modes are also discussed in the operator's manual.
You can't go wrong by following the information contained in the
model's operating manual.

Hi Scott. You may want to apply a tiny amount of light oil to the gears and shaft. I would use an ear swab. DO NOT spray any type of lubricant on! it will most likely get into places that it can cause problems. Be especially careful not to get any type of cleaner or lubricant on the circuit board or wires inside the VFO housing! This can cause the VFO to drift excessively, or other problems.

If the VFO knob turns easily and smoothly, I would not mess with it.

Just to add to that, when I got my TS-520 the VFO knob was quite notchy when turned - to the extent that in some positions it was almost like it had 2.5kHz channels! I did contemplate cleaning and oiling the very fine gears with something like clock oil, but found that backing off the knurled brass nut holding the shaft a tiny bit improved things immensely. It has a tapered flange that presses on a tiny ball-race, and (like all adjustable taper bearings) if it's overtightened will exert an enormous pressure on the bearings, making them stiff to turn.

You will have to neutralize them. The difference between 120 and 140 watts is so minimal that you would never tell the difference under any conditions.

I would recommend the ain't broke don't fix it approach.

Subject: [TS-520_820_530_830] Swapping 6146 Finals on two TS-830s

Hello Group,
I have two TS-830, one which seems to have been tempered (Chassis holes) and a second one unmolested. The first have the RCA 6146A which measure about 140W the second rig has the Sylvania 9146W which measure about 120W.

I want to swap them, but don't know if I need to neutralize them (Which I don't know how) before I proceed.

Any advice will be well taken.

Cheers,
KO6WW

I agree with Walt, a 20 watt difference is not going to be notice at the receiving end.

However, there is something wrong here. The maximum ICAS 2 tube rating for 6146As is 130 watts. The 830 with 6146A is pushing those 6146As too hard. I recommend reducing the maximum power output from the 830 with 6146As to 120 watts or less.

21184. Restricted and Distorted TX SSB Audio

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-08 18:54:11 UTC
From: Gordon
Topic: 21184 Message: 21184

I have a TS-180S here that is giving me a hard time. I know it is not an 830, but the circuitry is very similar other then the Solid State finals. The CW output is clean and pure, but the TX SSB Audio is Horrible. It is all restricted and Distorted. I have checked the MC-60 Mic on the 830 and it works Great. So it is not the Mic. I have checked the voltages on the first 2 Mic amps and they are exactly as they should be. Any suggestions where to go next?

Thanks,
Gordon

I agree with Gordon and the others-it is not worth the trouble to swap the tubes and you may shorten the tubes life. Since the first rig was obviously modified, I would be concerned that modifications were made to drive the tubes too hard. I would stick with the unmodified 830S until I understood the changes to the first unit.

In all seriousness, power isn't that important until you're talking orders of magnitude more power.

I have - as some may know, and here I undoubtedly invite the catcalls from the peanut gallery ("Got it off a cornflakes packet!") - a UK Foundation licence, which has a power limit of 10W on all bands except 136kHz. Now I can fire up my transmitter at 10W on 7MHz and see the signal on websdr - http://websdr.ewi.utwente.nl:8901/ - pretty clearly showing up as a bright line. I can get my mate with an Intermediate licence (hello, 2M0DIQ) to crank it up to 40W, and the bright line doesn't get a hell of a lot brighter, unless the conditions are very poor. If the band is closed, then no amount of power is going to make the trip from IO75TV to JO32KF, no matter how hard you try. If the band is open, I can show up in the waterfall with less than 5 watts. Power isn't everything.

A few people have mentioned having seriously high output power from their TS-[58][23]0 rigs. I shudder to think what the spectrum must be like with more than about 100W out - they must be clipping like blazes! If you're running much more than probably about 120W then you must be well beyond the linear region of the amp. You're certainly getting pretty close to what the HT supply can deliver. You might very well be using the world's most over-engineered fuzzbox...

Gordon MM3YEQ

Hi Gordon. What I learned many years ago in electronics school is that to increase your signal by 1 s-unit at the receiving send, you must transmit with 4 times the power.

For example. Say that you transmit with 1 watt and your friend has an S-1 signal on you. To give you friend an S-2 signal, you need to increase power to 4 watts. For an S-3 signal, 16 watts. For an S-4 signal, 64 watts, etc...

In my experience as an Amateur Radio operator, I have found that this holds true. I have also found that improving your antenna(s) is a better way to improve your signal than using an amplifier. The difference between 200 watts PEP (the peak wattage that most radios produce in SSB mode) and 1500 watts PEP (the maximum power output allowed for U.S. Amateurs who hold a General class or higher license) is about 1.5 S-units.

Correct. Scary, isn't it? You end up needing a lot of power to go not much further...

Exactly. One of the things I've noticed about the cross-pond QSOs I've had is that the people who I hear really well and who hear me are all using horking great 20m beams. If they're running the full-fat 1500W into it, then here in IO75TV with a wire dipole significantly less than a quarter wavelength off the ground and all the usual clatter and hash from cable boxes, wireless routers etc. then they are often S9+30, and my 10W is getting me reports of 5/6 or 5/6 over there. Good aerials work well on receive, too. You don't want to be a shouty deaf guy, do you?

High on my list of priorities for moving house is a garden big enough to put up an 80m dipole. The garden I have now is just too small for that. "Why don't you use a G5RV, Gordon?" Because - no disrespect to Louis Varney - it just isn't that great. By being a compromise to work on all bands, it doesn't work terribly well on any of them. On the lower bands, most of the RF ends up rattling up and down the feedline and you put out a perfect signal into next door's baby monitor and very little into the sky. There are other kinds of compact antennas out there, some of which look very hard to make repeatably. A good sign that something is too good to be true is a phrase somewhere on the designer's website saying "I don't know how it works, but it does!" - mmm, yeah. Okay. If you say so.

Getting back to the transmitters and pushing 120 or 140 or even 160 watts - do these people run their cars at wide open throttle for long drives? I wouldn't have thought so. I can't even see how the power supply can reliably push that amount of power. I'd be really interested to see the spectrum from one of these hybrid rigs when it's putting out 160W - but not mine, okay? 6146es are expensive these days.

Gordon

21190. TS-830S Fan operation?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-10 19:15:59 UTC
From: wohtex
Topic: 21190 Message: 21190

Couple of days ago I set my TS-830S back up and have been using it only on receive. Last night I was behind the desk and noticed the cooling fan wasn't running, radio felt cool but my TS-520S fan runs full time. Couldn't find this addressed in the manual or searching the group, does the TS-830S have temperature relay to turn it on when needed or is it supposed to run when the rig is turned on like on the 520? Thought I'd ask before I opened it up and started looking.

Bill,

The fan on the TS-830 receives power as soon as the power switch is turned on. It runs directly from a 100V tap of the power transformer and is not fused. There isn't any thermostat or relay involved.

Hi Bill,

I only had my 830 on last night in RX only, and the fan was busy going round and round.
I would guess there is something a miss here.

Kevin, ZL1KFM.

we are very lucky in the UK , the way we can measure power.
26dBW at the feed point. Moreover, a 1dB increase in power can and
frequently does make the difference between exchanging reports and not.
But if your going to push valves as hard as possible, you need to make
sure they maintain the HT and most importantly the screen grid voltage.
You also need to keep them cool.
IMO the Kenwood hybrids are unable to do all three when pushed hard.
If you really want to run power get on the proper bands and use that
big passive repeater with a path loss of 270 dB.

This is a good point. Perhaps someone whose beard is greyer than mine can explain how you actually measure the power at the feedpoint. My power meter is quite small, quite heavy and also probably pretty fragile so the idea of actually mounting it at the feedpoint and transmitting didn't seem like a great idea. That, and the feedpoint is about the height of a second-storey window so it's too far away to read anyway.

What I did was rolled out the cable on the ground, hung the power meter and a dummy load off the end, and fed varying amounts of power in while swapping the meter from the load end to the transmitter end, on each of the bands. It turns out that 50' of crappy el-cheapo RG58 only exhibits about .5dB loss at 3.5MHz, and about 1.2dB of loss at 28MHz, so I work out how much power to feed in at the bottom to get the right power out.

> frequently does make the difference between exchanging reports and not.
> But if your going to push valves as hard as possible, you need to make
> sure they maintain the HT and most importantly the screen grid voltage.

This is something that the TS-520 at least does pretty well, considering. I can't vouch for what happens when you push them extremely hard, but mine puts out a measured 105W at 210mA, 850V (using a real meter, not the rig's built-in one). The PA and driver valves are new-old-stock.

> You also need to keep them cool.
> IMO the Kenwood hybrids are unable to do all three when pushed hard.

At full power, the output cage does get pretty warm. I suppose the trade-off is having an almost silent fan that doesn't shift as much air, or having something that sounds like a Rolls-Royce Trent in full cry (step forward, Mrs Gordonjcp's combined laptop/space heater/hoverboard).

> If you really want to run power get on the proper bands and use that
> big passive repeater with a path loss of 270 dB.

By the time the sunspots are back I'll have moved to somewhere I can throw a decent amount of wire up. My current back garden is just the right size for an unobtrusive 20m dipole.

Hi Dave. No, I meant what I said, 200 watts PEP in SSB mode. Power in SSB mode is measured as Peak Envelope Power. This is harder to measure than a signal where a carrier is present, which is measured in Watts (RMS). Most HF radios put out approximately 200 wattsPEP in SSB mode, and 100 watts in CW (and/or FM mode), 40-60 watts AM mode.

The bearings are probably gummed with 30-odd-year-old oil. Carefully
cleaning and lubricating them with sewing machine oil might be a good
start. Don't just scoot them with WD-40.

Hi Martin,
Operating Manual specifies :
"PLATE POWER INPUT..... 200w PEP for SSB operation".

800V x 250mA(max. on voice peaks) = 200W PEP input power.
200W PEP input with Class AB1 at 60% efficiency gives 120W PEP output on a good day.

See http://www.vk1od.net/measurement/SsbTxPower/MeasureSSBTxPower.htm
for ITU definitions then page-down for a photo comparison of measurement methods.

Cheers
Dave f4eyk

****
Easy to take the fan apart...
If the armature shafts are all gummed up then I use some 600 wet sandpaper with synthetic oil on the sandpaper to polish up the shafts....
You can also roll up the wet sandpaper & turn in the brass sleeve bearings...
I then lube with synthetic oil (Amsoil) & put back together...
If it looks like it really got HOT then you might want to replace the fan....
I have the fan in nice condition for $22.00 plus shipping...
Let us know how it turns out..
Bob

21201. Digital Display TS-820s

Hello, To all that are haveing problems with digital display.

I think I have solved mine. My display was drifting constanly on all

bands and it got to the point where only one digit a nine or zero was

displayed. And sometimes it would display 19.000 no matter where the

VFO was turned. I thought for sure I needed to find a used DG-1 unit.

I got frustrated and removed the DG-1 unit from the chasis. Removed the

screws from the metal case that holds the lid on the DG-1. There are

two circuit boards inside. One of mine had about 5 solder joints that

looked questionable. There was an orange colored corrosion on the solder

joints that sort of crumbled when scraped with a small screwdirver.

Well I desoldered and resoldered thees joints and now the display is

working perfectly on all bands no drifting. Hope this helps others

having simular problems.

In addition to your findings, DG-1 failures can also be traced to dirty contacts between the Counter and Counter Mixer inside the DG-1's metal enclosure. DG1 failures are not limited to intermittent displays but failures elsewhere as well. Additional digital display failures can be contributed to one or more of the following:

1. Unlocked PLL.

2. Failure of the 9VDC supply.

3. Failure of the 14VDC supply which causes item 2 failure to occur.

4. VFO plug not plugged into the rear of the VFO.

5. Jumper plug not inserted in the rear 9 pin socket when the VFO-820 is not used. If the jumper plug is not available, a missing wire jumper between pins 8 and 9 on the rear 9 pin socket.

6. Broken wires at either end of the 9 pin interconnecting cable between the remote VFO-820 and the 820 itself.

7. Failure to use the jumper plug or, in the absence of the jumper plug, a simple wire jumper between the rear 9 pin socket, pins 8 and 9.

8. Broken wire or very dirty/oily/corroided contacts on the FUNCTION switch wafers.

9. Bad digital display tube or broken interconnecting wires from the display tube board and the Counter Mixer connection.

The most common source of digital display failure is item 7.

Erratic digital display coupled with instability in VFO tuning is not caused by a failure with DG-1 digital display but rather by a very dirty/corroded VFO variable capacitor shaft to frame connection. Corrective action is to remove the side panel on the internal or external VFO, which ever one is causing the instability, and give the shaft to frame connection a shot of contact cleaner followed by rotating the VFO knob a number of times throughout its travel. Once this is done, use canned air to blow away any excessive cleaner residue and dirt dislodged during the cleaning process then replace the VFO's side panel.

Drifting digital displays that shows up as a slow increase/decrease in frequency is not caused by a failure in the DG-1 but rather a drifting VFO. The VFO in the TS-820/TS-820S is powered by the 9VDC supply and changes, either up or down, in the 9VDC supply, affects the VFO's stability resulting in a change in the VFO's output frequency which affects the digital display.

In most cases, not all, instability in the 9VDC supply can be traced to aging D5 and Q7 on the AF-AVR UNIT. Replacing these components will significantly improve the VFO instability resulting is less drift in the VFO and the DG-1 digital display.

These are some of the common failures I have experienced with my TS-820S and DG-1 display. Your failures may include some and possibly other failures as well such as failures in the CAR1 and/or CAR2 circuits.

Hi Tripp,

VR2 is part of the RIT circuit and is used to adjust the zero point
for the control. Follow the RIT alignment procedure in the service
manual and you'll be fine.

Hi all,

I'm downsizing my shack so must sell my treasured Kenwood 820 line.

The TS-820S is very clean inside and out, with very little scratches or blemishes. The readout is bright.
I have cleaned all connectors, switches, pots, VFO, and oiled the fan. The output is 100 watts on 3.5 MHz with the original finals. This radio has had very low usage and is in excellent condition. No issues.
Comes with operating manual on CD and paper service manual $325 + shipping.

The R-820 is also very clean, with the following filters: Inrad first I.F. Filter is 400 Hz, and Inrad 2nd I.F. Filter is 400 Hz for CW, YG-88WS filter for SSB and the YG-88A 6 KHZ filter for A.M. and has VBT. The R-820 covers from 160 to 10 meters (no WARC) plus the 16, 19, 25,31 and 49 meter band for commercial SW broadcast. I have cleaned all connections switches and pots about one year ago. The condition is excellent with no issues, readout is bright. Comes with paper copy of operating manual and service manual $450 + shipping, (There were not a lot of these made)

MC-50 mic with 4 pin connector in excellent condition. $55 + shipping.

Thanks for looking! Photos available of all items. Please contact me off list.

Hello Tripp,

Lou's correct.

Before you perform the 3.3VDC adjustment on the AF-AVR UNIT, make sure you adjust the 9VDC first.

Good afternoon all you guys and gals,

I have a strange question, so please bear with me on this one.

I had a fellow bring his 520SE over because he saw sparks and smoke. After opening it up, I found under the final tubes a PC board. There appear to be two burned resistors I think. One could be a diode.

Here is the only way I can describe it.

One is connected to a point on the board marked "FG" and goes to an unmarked pad.

The second one goes to a pad marked "IPM" and the other end is connected to one of the 6146 tube pins, which is jumped to the same pin on the second tube.

There are no numbers on the board so I am unable to identify these parts. They were blown because of the final tubes being shorted. (At least one was)

I downloaded one of the manuals online, but it has no PCB on it, only regular wiring for a set of finals.

Do any of you have any idea what I am looking at, or possibly what the values of these parts are?

Thanks for any assistance that might be offered.
Mike-K5VSE

I forgot in the previous post, both the knobs for the NB and AGC are missing. If I get this rig up and running again, does anyone have these particular knobs? The switches are intact and working.

From: Lou Blasco
Topic: 20373 Message: 21213

Hi All,

I have a 520 and 520S on the bench at the moment and I'm having some difficulty adjusting the carrier units. I've found that the CW crystal adjustment interacts with the USB crystal on both sets and just touching the can of the CW crystal can cause the USB crystal to stop oscillating briefly. Grounding the CW crystal case kills the USB oscillator. Happens on both sets. The other two crystal don't seem to affect the CW crystal or each other in the same way.

Other problem is that I can't get the CW crystal to oscillate at 3395Khz. Both seem to run best at 3394.2 KHz and I can't get either to pull up to 3395. On both sets the LSB USB crystals can be adjusted to the correct frequency. T1 is adjusted for max output, voltages are fine on both boards and the AVR unit has been adjusted correctly. I've replaced D1 to D4 on the carrier unit in the 520S just in case one of the diodes was leaky. The radios work fine and on air reports are great so I'm not sure if I have a "real" problem with these sets.

Comments?

The design of the finals is pretty much the same between all versions of the TS-[58][23]0 rigs. Start from the valve base and work your way out - no matter how the unit is constructed, the valve pins stay the same...

My TS-530S has an intermittent annoying problem. The digital display will go blank, the indicator lights over the display (proc, etc.) will go dim and the receiver will go completely deaf (not even a noise floor). Changing the bandswitch (my first suspect) doesn't change anything.

If I whack the case with my hand it'll come back just fine.

I suspect a crusty connector or a cold solder joint, but I don't know where to start looking. Any suggestions?

Start at the power supply and work forwards, I'd say. Can you narrow it
down by tapping *gently* with a plastic screwdriver handle?

Hello Mike
You will find two details about TS820 who may reply to your question. You will find "FG" and "IPM" on the schematic ans the PC board picture so may be you will be able to solve your problem. The cathodes resistors generaly blow up with the shorted tube you had. They are 10 ohmd 1W.
Good luck

Hello Gordon,

You said the receiver goes dead when the problem occurs. I would bet the transmitter is also dead, no RF output, when the problem occurs. Remember, there are "common" circuits in the 530 that, if one or more of the common circuits fail, both transmit and receive functions will also fail.

The PLL Unit, IF Unit, VFO, RF Unit, AF Unit, and Counter Unit (digital display) are all powered from the 3.2VDC, 9VDC, and 12VDC LV supplies.

The "source" voltage for all 3 voltages is the "14VDC" supply. Consequently, a failure in the 14VDC supply will affect all 3 voltages. An intermittent short to ground in the 14VDC supply can easily cause the symptoms you are experiencing. When this occurs, both transmit and receive functions will also fail.

Therefore, I suspect a problem in the 14VDC supply on the Rectifier Unit.

Mike W5RKL

Thanks Robert,

Another fellow sent me a PDF picture of the board from an 820 and they appear to be exactly the same as the 520. The only thing he told me was that the resistors were 20 ohm. Now I need to determine just what resistor burned and find a parts list. I will go out to my shop and figure that out and make a further post.

Thanks to all who have offered help so far. It is greatly appreciated!

I am embarrassed to say it was a lack of operator maintenance, a good cleaning and a light weight oil has it humming away. I have had the radio for a couple of years and even thou it has not been used extensively I should have paid more attention to basic maintenance. Thankfully I caught it before any damage was done.

The "FG" designation means "FINAL GRID" and the "IPM" designation means final amplifier's "IP METER". The "IPM" meter connection measures the final tube's "cathode" current which is the same as the final tube's plate current.

The "FG" connection is where the final amplifier tube's bias voltage is applied (through the rear panels bias pot).

If one of the final tubes was shorted then that is most likely the reason one or both of the 10 ohm 1 watt resistor were damaged. Replace "both" resistors, not just one, even though one may appear to be OK. Metal Film resistors will work fine but do NOT increase the resistor's wattage. Replace both with 10 ohm 1 watt resistors. Do NOT increase the wattage of the replacement resistors!

Hi Mike,

Thanks for the info. I just came back from my shop. I compared the 830 board that a fellow sent me a copy of and the existing 520 board. They are similar in some ways, but there are differences. The resistors you mentioned, in this particular rig are probably 1/4 watt or maybe 1/2 watt at most. They are burned to an open state. I went through all the resistors I have on hand, and could not find a pair of 10 resistors. Guess I'll order a few on Monday. There are a couple of others that look suspect that need to be looked at as well.

Have a great weekend es 73,

Hi Mike & All on the thread,

Mike, in case you are unaware of it there is a very good web page for hybrid owners that explains much & offers parts that are of high quality and mate with the Kenwood hybrids. It is run by Ken Kemski & is

www.K4EAA.com

There are also other web pages run by members of this reflector that are very good and have much info. Gordon, who has many files in the files section of this group and of course Mike who you've already been in contact with are very helpful.

I've had great success with the parts from Ken Kemski (the giant size D schematics are good for tired ol' eyes & make great wall art for the shack.).

Good luck & much DX with your hybrid,

Vy 73,
Mike K8SYN

Hi Mike-K8SYN,

I think I found what I need on Ken's site. Now I find that my printer is out of ink, so have to wait until tomorrow and print the board out. It looks like the one I actually have. I hope to get this thing working one of these days. The receiver works great. I will begin my search for two of the lever type knobs that fit the switches for the NB and AGC controls. Both are working, but missing the levers. That will only happen if I can get the transmitter going again.

Thanks again es 73,

Mike (K4SVE)

The final amplifier cathode resistors in the 520, 520S, and 520SE, are ALL 10 ohm "1 watt" resistors. They are not 1/4 or 1/2 watt.

I do not recommend using a TS-830 schematic/final amplifier board diagram when servicing a TS-520SE.

The 520SE manual is available free at the following website:

http://www.n6wk.com/kenwood/

Mike-W5RKL

Yeah, I found there was a difference in the two. I did find N6WK's site and downloaded the right info. All I need to do, it get ink for my printer. I tried tonight to print the one page that has the final PCB board, and found out I was out of ink. I hate it when that happens. As far as I was able to tell there in one 100 ohm resistor burned, and I have not identified the second one yet. I'll be able to do that tomorrow after a visit to our local Wally World. I am really anxious to get this one on the air, as years ago I had the complete 520 set up. VFO, DG-5, Speaker, and transceiver. I do remember that the receiver was pretty hot for and older rig.

Thanks es 73,
Mike-K5VSE

Hi Mike,
I tried to send you yesterday the schematic and PCB trace for the TS520SE, but I forgot that all "attached" data will be retired by Yahoo and my message was a little bit incomprehansible.
Well sorry but I see on the list that other Om had the sa me idea as mine and all is best.
The 100 ohms R you just noted should be one of the screen grid resistor.
There should be 2 100 ohms 1/2 W for the screen, 2 10 ohms 1 W for the cathodes, another 100 ohms 1/4 Wfor the grid polarisation and one 3,300 ohm also 1/4 W for the plate curent mesurement
I had almost the same problem as you have with a TS820S, and I rewired the PA PC board and evidently changed the tubes and one PA coil switch wafer that was burned (and caused all the disaster!), before putting it back on the air. Since then, I sold it in perfect working
condition!

Thanks Mike and Lou I went back and did the RIT allignment and also started with the 9 volt adjustment and then the 3.2 volt. I did every adjustment that could be done with a volt meter including the band adjustments for 3.2 volts on the PLL board. I still had no improvement in the digital display that was constantly droping in and out. So I removed the DG-1 unit again and discovered the (x54-1150) board had very loose screws holding it to the metal chasis.I don't know how I missed it before, one of those late night eye strain and fatigue things. I cleaned the contacts between the two boards and retightened the screws put back in and presto! Now the display is working like new. I have more problems to tackle with this old radio but some of them maybe antenna related, such as week recieve. Im haveing to turn the AF gain a lot higher than usuall to hear. So untill I get more of the proper tools to make the adjustments I will have to live with it.

Thanks again for the help.

Thank you Robert,

I have just come back from the shop and found the following. R4 is 3.3k and is open. R1 is 100 ohm and is also open. I will replace these and both final tubes. Then we will see where that might lead me. I will check the band switch before applying power to the rig. The next thing I need to find if the rig works, are two of the levers for the NB and AGC switches. I probably will paint the cabinet, as it is pretty well scratched up. At least the little door on the side is still there! Most of them I've seen are missing the door.

And to all whom have offered help on this rig, my heartfelt thanks. It is really appreciated.

Has it got any funny properties, or is it just a generic silicon diode?

A 1N4148 is 75V 200mA, so that should do the job without breaking a sweat - *if* it's just a plain ordinary silicon diode.

Any silicon diode with a PIV rating of 35VDC at 100ma or higher will work as a replacement.

OK folks,

My last question! Does anyone have a legible copy of the final board for a TS-520SE. I downloaded several versions, but can't read the value of R4. It is either 3.3 or 33k. My copy is blurred and makes it difficult to see. I have identified the two burned resistors as R1 and R4. R1 is 100 ohm, and as stated R4 can't be read on my drawing. They both appear to be 1/2 watt resistors. If I'm wrong, please advise. The cause of them opening up was a totally shorted final tube. I will replace both finals and probably the driver after the resistors are replaced.

I have received a lot of help from members, and for this I am grateful. Thanks to all who have responded. Hopefully I will have the rig on the air by the end of the week. This one is worth the time and effort, as it even has the little side door. It is missing the lever control handles for the NB and AGC, but the switches are intact and working. If all goes well, I will also order the paint from the fellow in MO who sells paint for various rigs. I used him for an old SB-200 that now looks new.

Mike,
There is a FREE program called PDF-Exchange Viewer that does a much
better job printing out schematics then Adobe does.
http://www.docu-track.com/home/prod_user/PDF-XChange_Tools/pdfx_viewer
Many times, the adobe print is not clear enough to read, but this
program is because it uses TILE printing.
Check it out!

21240. TS-520SE problems

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-18 22:48:55 UTC
From: Mike-K5VSE
Topic: 21240 Message: 21240

Well, today I replaced R1 and R4, as well as the finals. Now, no matter where I put the multi-meter switch, I can key the transmitter and the meter will peg. It will not read the HV. I measured the HV and it's just over 900VDC, which I assume to be close. There is absolutley no output,as I have a scope across my dummy load. I have not connected an antenna, but can hear the calibrator very well,so I have to assume the receiver is working. It looks as if there is more wrong on the PCB for the finals than just those parts that were obvious. I will need to go further in my troubleshoting to locate the problem. I have not found the relay yet either. Must be hiding in there somewhere though, I can hear it when keying the transmitter.

If anyone has any suggestions please let me know, but in the mean time I will continue searching on my own.

Thanks to all for the help.

73,
Mike

So, the meter hits the peg whether it's set to ALC, IP or RF, but
doesn't read when set to HV?

First off, make sure the bias pot is at minimum - it's *very* sensitive
and should only be increased *slowly* with the transmitter on until the
meter reads 60mA.

I guess if RL2 was stuck in receive then the meter could only ever read
ALC and the pi network would never be switched to the aerial, which
would cause a certain amount of distress. Incidentally I think the
contacts for RL2-1 may be drawn the wrong way round - I would have
expected the receiver input to be grounded when transmitting. As it's
drawn, in transmit the NC terminal of RL2-4 is grounded by the NO
terminal of RL2-1, which looks odd.

It's a bit hard to follow the busy parts of the circuit, but it looks
like if RL1 was stuck in receive then receiver AGC would be switched to
the transmit ALC line through the AGC amp (Q7, Q8). That might well
cause some odd stuff to happen.

Gordon MM3YEQ

RL1 is located under the VOX Unit board on the top left
rear of the 520SE. Remove the VOX Unit board and the forward plate
covering the chassis to gain access to RL1.

RL2 is located on the bottom of the chassis at the end of the
band switch shaft in a small metal enclosure between the large
metal enclosure and the rear panel.

Good morning Michael,

Thanks for the description for the location of both the relays.

NO, the fuse does not blow.

I'm on the way out to my shop that is about 200 feet from the house. I wish I had my computer out there as well, because I do have quite a bit of info stored on here relating to the 520. The next best thing is to print the whole manual off to take with me. Being on fixed income, I have to wait until tomorrow to get some ink, as I'm out at present. I have found a guy that has a parts radio who is willing to give me the board from it, and that might be the way to go. I wish Kenwood had printed the pin numbers and part ID's on the board. Would have made tracing the schematic a lot easier. Oh well, I'm too stubborn to stop now, and will find the solution eventually.

Hi Mike,
Too bad, but be cautious!!! Look first at the commande grid polarisation. Should be something arount minus 100 V on receive, down to -45 to -55 V in transmit. When you turn the polarisation pot, you can go from 0.00 mA to full scale on the plate curent meter if the new PA is working correctly. Look also at the rectifier boards. The HT (+900V) is OK going down to +800/+820 V under load.

Topic: 21246 Message: 21246

The more I work with it the more I am impressed. I have never even tried to work on my other rig. This TS 820 is built like nothing else I have seen, maybe a Collins. Easy enough to work on and large enough to work with. I am in no way ever going to be able to work on surface mount parts. The desing is straight foward and at times I am impressed with its ability to work signals in the enviroment we are in today. I put in a another new INRAD filter and with my TIMEWAVE DSP its hard to beat. I rarely use SSB, but I still cant believe for 30 year old gear it is quite good.
Let me also say that you must be careful about winning bids on eBay for filters. The last three I got were all bad, and the others I believe are damaged or lightening must have gone through it. The performance was not there. A quick replacement with a known good one showed the difference. I hope your luck on eBay is better than mine. To bad Kenwood has quit producing filters for older gear. I suspect the meter, in transmit, is displaying the receiver's full cut off bias, not ALC voltage.

The only time ALC voltage is produced is when the grids of the final tubes are "Positive", never when the grids are "Negative". ALC has nothing to do with nor is it used in receive.

I agree that relay RL2 may not be energizing. A visual inspection can determine if this is true or not. RL2 is located inside the small metal box at the end of the band switch shaft on the bottom of the radio.

Q7 and Q8 on the IF Unit are not ALC amplifiers, they are the "meter" buffer/amplifiers.

Thanks Mike W5RKL

The relay could well be the problem. It does not read the HV, but when I push the PTT in the HV position, it still pegs. I measured the plate voltage, and it's close to 900 VDC. Seems to remain constant in the keyed mode, so I will have to assume it is not switching from RX to TX even though I do hear one or the relays. Will check the second relay this afternoon. I also let some more smoke out of it. Looks like R70 and R71 burned while it was just sitting there as I was reading the schematic. What's next? HI HI

Hello to all,

I have come across two brand new unused filters. One is a Kenwood YK-88S SSB Filter

The other is an International Radio Inc. (INRAD) Model 88H400 BC
This one has had a small PC board mounted to it, according to it's box in 1998. Has a frequency of 8830.7 marked on the label.It looks like the right size to fit my TS-520SE.

Does anyone know what rigs these are used in?

Thanks

Mike-K5VSE

Hello Mike,

both filters are not for a TS520, because the if frequency for this rig is around 3 Mhz ,if I remember correct.
Kenwood changed the if frequency with the TS820
and the following rigs e.g. TS530 and TS830, 120 and 130
and the newer rigs TS 450 and TS850.
The newer rigs had the possibility to plug in the filters,
but there was no difference at the filters themselve.

all the best and 73

A blown Q10 on the RF Unit can also cause both R70 and R71 to fail.

A good Q10 on the RF Unit will have about +3VDC on the Collector and
-92VDC on the emitter and base in receive.

In transmit the emitter and base voltage of Q10 will be approximately
-52VDC and the collector will remain at approximately +3VDC. If,
however, Q10's Collector voltage measures -92VDC in receive and
-52VDC in transmit, Q10 is blown.

A shorted C1 on the Final Unit, .001ufd bypass capacitor for the "FG"
bias supply line, can contribute to R71's failure and prevent bias
voltage from being applied to the final tube grids. If C1 is shorted
there will be very little, if any, bias voltage on pin 5 of the final
tubes.

Depending on the schematic/manual you have, R1 and C1 on the final
unit, may be labeled in reverse "R1" for C1 and "C1" for R1. Both
of these components may also be labeled "R1". Check your schematic.

I recommend turning the Heater switch OFF then Measure the voltage at
the final unit's "FG" connection. It should be a negative voltage at
approximately -90 to -100VDC or there bouts.

I was in QSO in a net, when I noticed the digital display "scanning".
i.e displaying all digits from 1.800 to 95.999 Mhz (as far as I can see, it happens very fast) I figure it is temperature related and in the display unit.The transmit and recieve frequency stays put.Maybe bad cap, crappy plug connection. Any clues guys??
Thanks,
John

Hello. Need help please. I have a ts-830s that was working, blew a fuse while transmitting and now have several problems. Have checked voltages and seem to be okay (with tubes out). Put in a new set of finals as suspected a final problem as the power supply seemed okay. Went to tune the finals and find the alc off scale even with the carrier level minimum. Any suggestions about what to check. Thanks in advance. John wa5fac

Hello John,

You said,

"Have checked voltages and seem to be okay (with tubes out)."

What voltages did you check and where did you check them at?

Did you check the voltage in both transmit AND receive?

What you failed to say is what the "IP" meter indicated in Tune mode,
or any mode for that matter. What does the "IP" meter indicate?
The final tube must be in their sockets and the plate caps attached
to obtain an "IP" meter reading in any transmit mode.

Is the "IP" meter also "off scale" as well?

If the "IP" meter is also off scale then most likely the bias supply
is bad, one or both bias filter capacitors, C5/C6, are bad. Diode D5
can also be bad. C5 and C6 are 33ufd 160VDC axial lead capacitors and
D5 is a simple silicon diode with a PIV rating of at least 200VDC.
The bias supply is the "-C" supply on the Rectifier Unit.

If the bias supply fails then there is no bias voltage applied to the
final tubes and the final tubes will conduct heavily in both transmit
AND receive causing the fuse to blow.

I would first clean the Counter Unit plugs and pins that plug into
the PLL Unit and the Counter Unit.

The PLL Unit is the long PC board on the bottom right, 830 turned
upside down and the front panel facing you.

The Counter Unit is on the top of the 830 chassis, between the
front panel and the HV filter capacitors.

Use caution when removing the plugs to ensure the wires do not pull
out of the plugs. Also be sure you plug the right plugs into the
right pins.

Mike thanks. You are right, I did not give enough info. In the interim we changed the finals and driver again and the problem seemed to go away (but don't know why). I did not loose the bias supply and had read prior posts about that so it was first to be checked out.

Now, I have good drive and tuning. However, my frequency shifts about 6-800 cycles from receive to transmit. Any suggestions about where to look for that one. jm

It's possible, John, the 830's "RIT/XIT" control on the front
panel is turned ON causing the shift in transmit frequency verse
receive frequency.

It appears the driver tube was the source of your problem, most
likely it is shorted internally. A tube tester that tests for
shorts can determine if it is shorted or not.

Hi Ken,
Page 21 of this Manual shows exactly how to calibrate the Digital
display to read correctly.
http://www.n6wk.com/kenwood/TS-830S_Instruction_manual.pdf

It won't take much adjustment to move it .1 or .2

Thanks Mike, W5RKL, for replying to my post. The problem was indeed dirty plug connections on the PLL unit.
Now, on the next thing!
While inside the rig, I found a wire cut. This wire goes between the AF-AVR board, plug 6, pin 4 (TOF) and RF board, plug 6, pin 1 also marked TOF. Does anyone know what this mod is for?
Thanks,
John

John,

The cut wire enables transmitting on the WARC bands, 17 and 12 M. See page 28 in the user manual.

Never worked on a 830 before, but looking at schematic following the TOF line on RF board it goes to the band switch. Guessing being cut enables the WARC bands.

Thanks Mike, W5RKL, for replying to my post. The problem was indeed dirty plug connections on the PLL unit.
Now, on the next thing!
While inside the rig, I found a wire cut. This wire goes between the AF-AVR board, plug 6, pin 4 (TOF) and RF board, plug 6, pin 1 also marked TOF. Does anyone know what this mod is for?
Thanks,
John

Hello to all. I have a ts-830s that has no alc meter indication when tuning the grid drive (in tune position). None on any band. Tested the driver and substituted a different one with no change. Also tested voltages on the driver socket (tube out) and all okay but pin one shows 0.0 in both receive and transmit.

I need help to know where to go first and what to look for. Thanks in advance and glad to have your help. john wa5fac

Hello John,

Check resistors R15 and R16 (both are 15K 1/2 watt) on the Rectifier Unit. These resistors are used to lower the final tube's screen voltage in TUNE mode. If one or both resistors have significantly increased in value, the ALC meter indication in TUNE mode will be quite a bit less, if not zero, regardless of the CAR control and DRIVE control settings. RF Output in TUNE mode will also be affected. However, if tuning the 830 up in CW mode produces good output, replace both R15 and R16 with new 15K 1/2 watt resistors. Metal film resistors will do fine.

Mike thanks for the quick reply. I will try the resistors tonight and report back. I will say, that there is no output at any position on grid adjustment in tune position and that seems to suggest not a meter problem (this is using an external meter on the dummy load). jm

21270. TS-820S Run away Idle Current

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-26 20:34:28 UTC
From: Gordon
Topic: 21270 Message: 21270

I have an 820S here on the bench that is driving me nuts. The Idle plate current runs away(goes off scale) in USB but will go as low as 80ma in LSB. I am convinced it has something to do with the Carrier balance adjustment on the IF board, but I am at an end. Any suggestions out there?
I have tried new tubes and still the same thing. If I don't turn it off it will blow the fuse after a few minutes unless I leave the SG switch off. Then it does not blow the fuse.

Thanks,
Gordon

John,

When you say "no output at any position on the grid adjustment"
I assume "grid adjustment" is when you adjust the "DRIVE" control
on the front panel for a peak ALC meter indication.

R15 and R16 on the Rectifier Unit provides a voltage divider. At
the junction of R15 and R16, the "lower" DC voltage is applied to
the final tube screens during TUNE mode. This puts less stress on
the final tubes during tune up. After tune up, placing the mode
switch to CW, USB, or LSB, produces normal screen voltage level
to the final tubes.

A quick way to determine if R15 and/or R16 are bad without removing
the covers is to place the meter switch to "IP", mode switch to CW,
CAR control to 9 or 10 o'clock, and key the radio. The IP Meter
should indicate between 80ma and 150ma. Adjust the "DRIVE" control
for a Peak IP meter indication then adjust the PLATE control for a
DIP should produce RF Output on your external watt meter. If your
radio produces the indications mentioned above then replace both R15
and R16 and you will fix your problem.

Mike, tried your suggestion but just see bias current (about 50-60 ma of plate current) when tested as you suggest. No output and no deflection of the IP with grid tuning.

My receiver is also very weak so suspect this is an injection problem with some common problems on receive too. jm

From: w5rkl
Topic: 21270 Message: 21273

Afternoon Gordon,

Removing ONLY the driver tube should cause the final IP idling current to be normal, 60ma. If this is true then you can eliminate the final amplifier as the source of the problem.

Have you connected a scope and/or frequency counter to the IF Unit IF-3 plug pin 2 connection (TIF)? If the TIF connection produces a frequency of 8.8Mhz then the balance modulator is not balanced allowing the carrier generator signal to mix with the VFO producing the 8.8Mhz IF signal at the TIF connection even with no audio output from the speech amplifier.

Turn the MIC gain to minimum, remove any microphone from the front panel MIC socket, adjust the carrier null for minimum RF. If the problem is still there, then my initial thoughts are as follows:

1. Noise is being generated from the speech amplifier even with minimum MIC gain setting.

or

2. One or more diodes, D26, D27, D28, and/or D29 in the balance modulator on the IF Unit have failed.

Just a couple of thoughts.

Mike W5RKL

John,

How are you keying the radio in CW mode? Are you turning the "SEND"
switch on the front panel ON with a CW key or keyer plugged into the
CW socket on the rear? If that's how you are keying the radio in
CW mode, remove the CW key/keyer from the rear of the radio then turn
the SEND switch ON to key the radio. In CW mode you must close the
CW key or cause the keyer to key the radio. Simply turning the SEND
switch ON in CW mode with a key or CW keyer plugged into the rear
CW socket will not produce any output.

Also, if setting the CAR control to 9 or 10 o'clock does not produce
an increase in IP current, adjust the CAR control to a higher setting
and try again.

Hi Mike,
Removing the Driver does help, but it still acts strange.
When the driver tube is out and I check the idle IP, It at first
may read 70 to 80 but then slowly goes back down to 60. If I wait a
minute, do it again and it does the same thing. However, it no longer
runs away and blows the fuse with the driver out.
I turned the Mic gain all the way down and the compressor all the way
down, even though it is OFF. There is NO Mic connected.
Next step is to check the 4 diodes I guess.
My Frequency Counter shows NO reading on the TIF terminal.

73,
Gordon

Mike, okay on your suggestion. I have no key installed and also have tried the carrier all the way up as well. I believe there is a common receiver and drive problem as the receiver signals are way down and no drive on transmit. jm

If one or both resistors have significantly increased in value, the ALC meter indication in TUNE mode will be quite a bit less, if not zero, regardless of the CAR control and DRIVE control settings. RF Output in TUNE mode will also be affected. However, if tuning the 830 up in CW mode produces good output, replace both R15 and R16 with new 15K 1/2 watt resistors. Metal film resistors will do fine.

Is the PA unstable and taking off perhaps? Can you run through the
neutralization procedure and see if that makes a difference?

El siguiente mensaje lo envie a varios "usergroups" en Yahoo a los que pertenezco. El mismo fue enviado en ingles para la circulacion general. Ademas los enlaces ya fueron actualizados con las fechas y horas del evento.

El mensaje lee como sigue:

"To all Radio Operators:

KP3RE Special Event Station – Jesus T. Piñero Museum

The "Radio Operadores del Este (RODE) Amateur Radio Club will be signing as KP3RE from 1300 UTC to 2000 UTC on 10-15 and 20 meters. The team will be using buddisticks, buddipoles and other antennas during the operation. Also, WARC bands (12 and 17 bands) will be used based on propagation conditions. The operation modes are: Voice, CW and digital (PSK31 and Hell). Look for the DX Spots on the Cluster.

The Special Event Station will commemorate Jesus T Piñero as a the first Puerto Rican Governor appointed by the President of the United States in 1948. Also, Mr. Piñero, was one of the few Amateur Radio operators in KP4 Land, during the first decades of the 20th century. The Special Event will take place at his home, at present a museum.
QSL via www.qrz.com and for more information regarding frequencies look under special events tab on http://kp3re. tripod.com.

73's and see you on the bands.

KP3RE Special Event Team"

Morning Gordon,

Removing the driver tube did not produce the results in the Final
Unit that I expected.

Removing the driver tube essentially blocks the flow of any RF
signal from the IF Unit to the final amplifier which should have
resulted in a stable 60ma idling current in the final tubes. The
initial rise to 80ma then settling back to 60ma in the final
tubes is not normal.

Lou has a good point, check the final neutralization.

At this point I do not believe the balance modulator or any of the
4 diodes, D26 thru D29, are the source of the problem.

A check of the power supplies, using a scope, for the presence of
AC ripple should also be done.

I also would not rule out bad grounds whether through a mounting
screw on the PC boards or any of the many plug/pin connection.

Easy enough to check and worth doing *anyway*, but why would it make it only run away in USB? Or, am I misremembering the original problem...?

Hi Gordon,

The plate current should not vary without RF drive. Gordon also said
that the fuse blows unless he keeps the SG switch off. Without RF
drive, the only way that the tube current can vary is a bias
problem(supplies etc), bad tube(s) or an unstable final stage. I
believe that an unstable PA can sit there for some time then suddenly
burst into oscillation. These oscillations "can" make the tubes pull
a large amount of current, enough to blow the fuse and it can happen
in an instant. This follows Gordon's description of the fuse blowing
after a few minutes. Everything seems to point to the finals. I agree
that the difference in tube current between USB and LSB is puzzling
but the tube current does vary for both. Until the tube current is
stable and the fuse stops blowing I'd be looking around the PA.

From: jsloss
Topic: 21282 Message: 21282

RF Proc switch pushed in - corrrect transmit modulation w/ normal ALC action. With switch pulled out no modulation or ALC action, regardless of where
Mic Gain and Comp controls are set.

COMP ON-OFF switch is good confirmed by swapping IF modules w/ another 820S.

Any ideas of a good starting point on the IF board?

Hi Mike, Gordon and Lou,
Well, looks like I had TWO problems.
I swapped out the finals with another used set and then started tightening all ground screws and removing, spraying with De-oxit, all the connectors. What I ended up finding is/was a broken wire coming off the RF board that goes to FG on the finals board. When that terminal lost contact, the Finals went WILD !
Once I replaced the little spring connector inside the plastic connector, I now no longer have run away Idle current.
There is a different idle current from USB to LSB by about 10ma but it is stable and I know I can get that part equal by doing the carrier balance adjustments. I have run into that before. Once the null is set, they will be equal again.
Thanks for the help. Now to go back and start the Alignment over.

73,
Gordon

That's great Gordon! I knew you would find the problem.

Anyway, congratulations Gordon and you are right, aligning the
sideband balance will fix the difference in the idling current.

I still have a slight PLL problem with my 820, USB sounds different
than LSB, not the same receive "tone" in receive. That's more than
likely the sideband balance which I have not gotten around to. One
of these days I'll put it on the bench.

By the way, I would recommend checking the AF AVR Unit's 9VDC on
AF1 pin 1 (adjust VR4) and 3.3VDC on AF2 pin 6 (adjust VR1).
If your 820 drifts a bit more than it should, replace Q7, 2SA496Y
and D5, 6.1V zener on the AF AVR Unit then readjust the 9VDC then
the 3.3VDC and you should see a significantly improvement in the
drift. I did that to my 820 and the drift is back to factory specs.

Anyway, congratulations Gordon.

Thanks Mike,
All has gone well until I get to the carrier Suppression adjustment.
The first part goes well.
I adjust for maximum output on 14.175, then switch to USB and adjust VR5
and TC2 for Minimum on my scope. No Problem there,
but when I switch to LSB, the reading on the scope is Way high and
nothing I do can get the two (USB & LSB) to be the same.
I did the Neutralization and that was easy. Just can't get the Carrier
Suppression to show the same on the scope. On the 830's i work on, I can
always get the USB and LSB to be exactly the same on the scope.
The Idle current is equal now on LSB or USB however.

73,
Gordon

21286. CAR 1 Adjustment for TP5 on IF unit

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-28 03:20:25 UTC
From: trippkj4bkd
Topic: 21286 Message: 21286

Hello, to all.

Attempting to adjust CAR unit 1 x50-1310 to 50mv measured from TP5 on x48-1150. I am currently reading 3.5 to 5.5mv fluctuating with no adjustment. Now this is on the 200mv scale on my DVM. I may be mis-interpreting the reading not sure. However I can't find T1 on x50-1310 as it is under x50-1320 board and the holes thru from top baord 1320 to bottom board 1310 read USB,LSB and VR. I am not sure if one of theese is T1. If not.How do I get to it? I can see T1 on CAR unit 2.

Any advice is most appreciated.

Tripp

Hi Tripp, First of all, you need to be using a VTVM or a scope to measure TP5

The Carrier unit has two screws. One from the RF Board side, and the other from the bottom. The complete unit will pull out, while still plugged in so that you can get to the underside of it and adjust the controls on CAR-1 as well as Car-2

Hope this helps,
Gordon

21288. TS-820S/SB-200 works but not TS-830S/SB-200

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-28 13:46:12 UTC
From: k5xrf
Topic: 21288 Message: 21288

Hi, I've been using my TS-820S to successfully drive my SB-200 amplifier for quite a while now. I'm having a problem though when I attempt to drive my SB-200 with my TS-830S. The problem that I'm having is that whenever I connect the tip of the RCA jack of the relay control to the center conductor of the SB-200's relay jack it keys the amplifier (without making the common shell connection and with no ALC connection). Both the TS-830S and the SB-200 are connected to a common ground using the same method as the TS-820S. I've checked the cable that I bought against the figure in the TS-830S manual and have checked it for continuity and shorts. All seems OK. The cable's DIN connector is connected in the "remote" socket, the one next to the fuse holder.

Has anyone else had a similar problem? Any ideas on why I can interface the SB-200 with the TS-820S just fine but not the TS-830S? I'm still suspicious of the cable but wonder if it could be something else.
73,

Jon K5XRF

Hello Jon,

I suspect you have the 830's remote connections wired wrong.

The amplifier's relay should be wired between pins 1 or 4 and pin 5
on the 820's remote socket. Relay voltage to pin 5 and ground to
either pins 1 or 4. Pins 1 and 4 are ground.

The amplifier's relay should be wired between pins 2 and 4 on the
830's remote din socket.

21290. TS-820 - Erratic VFO on 80 meters

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-28 18:20:33 UTC
From: Jim
Topic: 21290 Message: 21290

I've come across an odd situation with my TS-820. What I'm about to describe only happens on 80 meters and only when the VFO frequency exceeds 3.899mhz.

If I go to this band from any other band and tune-up the band to say 3.920mhz, the vfo becomes erratic. Only a slight touch will send it to 4.000 or sometimes the digital display will completely blank out as does the receive audio. This does not appear to be just a quirky digital display because the receive frequency does change in step with the actual readout. I can ever so gently keep playing with the vfo knob and eventually I can to the frequency I want.

80meters is the only band that this happens. Everything else on this transceiver seems to be working very well. Any ideas on what might be making it do this on this band only?

I was also considering buying the TS-820's matching External VFO but wanted to first see if anyone had any thoughts on what it might be.

I don't think it is something as easy as a dirty bandswitch... I've jiggled it when I was up around 3.920 and it didn't seem to have any affect.

Thanks
Jim

Jim,
It sounds like the Wiper is dirty on the VFO.
The reason it probably only shows up on 80 meters that high up is
because none of the other bands except 10 or 15 meters would go that
high on the VFO scale to stay in the band.
Try it on 21.420 or 28.420 and see if it does the same thing. If so, I'd
look at cleaning the wiper.
There is an instruction PDF on my kenwood Files site that tells and
shows how to do it on the 820.

73,
Gordon

21292. TS-830 and ATU Help

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-28 22:10:25 UTC
From: Gmail - Kevin, Natalia, Stacey & Rochelle
Topic: 21292 Message: 21292

Hi All,

I am in need of some help, advise really.

I have a TS-830 with no ATU.
I also have a TS-480S/AT with the built in ATU.

Okay I used to many years ago have a Dawia ATU (think thats spelt correctly), and when I upgraded my radio of the time to a Kenwood with the builtin ATU I decided to get rid of it, never thinking I might need it again.
Well here I am now with my TS-830 and a 80mtr full wave horizontal loop at 7mtrs above ground.
I require that ATU now to use it to it's fullest. I don't want to get too much into it but I have fed it directly with 50ohm coax. Some say open-wire, others say caox to a 4:1 balum, and other direct with coax.

The problem I have it, there are many types of ATUs, L-match, T-match and Z-match, and I am sure there are others. My search brought up these 3 mainly.
All three look fairly easy to build, but which one is the best for my equipment? What do others on this group prefer to use with their TS-830?

I could go out and buy one of those auto tuners from LDG Electronics, which appear to be fairly priced. Would save me mucking around with knobs.

Thanks for any advise given. BTW I do not have any parts for the ATU, but I have a ham equipment sale coming up in August which I know will have the stuff.

Regards

Kevin, ZL1KFM.

Joe,

Thanks for your reply.
I did understand about the "pi" tuner inside the radio for tuning the tube, but I did not know I could use this for the antenna.

Next question, what would be the recommendation for the balum, a 1:1 or 4:1, I have both available.

Regards

Kevin.

The feed point impedance of a dipole is around 72 ohm so using a 1:1
balun will get you in the ballpark. The matching stage in the 830
will handle this setup with ease.

Hi.. I'm using the Kenwood AT 230..it works great with my homemade Off center dipol for 160m hanging about 8m over ground.. Before I got the 230, i used a homemade z-match, but it could not operate on 160, so i build a CLC match, and it worked fine.. but.. still have 3 handles to move when mowing from one band to another,, maybee a autotuner can do the job,,

21298. Scam Warning to User Group

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-29 05:09:31 UTC
From: Bob
Topic: 21298 Message: 21298

Just wanted to warn everybody on this users group to be careful about scammers. I got louered in by one that posed as tho his house burned down and that he lost all his equipment in the aledged fire. Hopefully he won't reappear, but if he does, his name is:

John Acuff
3284 N.Co. Rd. 275 E.
Logansport, IN 46947

This guy told his story on this user group in an effort to get equipment from unsuspecting, well intended hams, to regain some of his losses. Of course, this turned out to be bogus.

In good faith, I sent this guy a TS-520 free of charge and he was to reimburse the shipping...Never heard from him again. Needless to say, I feel pretty foolish.

Anyway, just wanted to let everyone know that this guy is a con artist...be careful!

Bob

21299. Capacitor Replacement on TS-530s C23 & C24

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-29 13:19:07 UTC
From: Peter
Topic: 21299 Message: 21299

I recently purchased a TS-530s. One of the two capacitors had been very poorly replaced with a 100 mf and 85 mf caps in some sort of series piled high with glue gun glue or silicone goo. The other cap is the original and looks tired. I would like to replace them both. Unfortunately for a novice like me there are changes to the wire colors and locations that make repair more difficult. Can someone guide me with this repair. I am concerned about getting the polarity correct and ensuring that the resistors and small disc caps are installed correctly. The existing red & green wires may now be too short and may need replacement. The best pictures I have found are on http://www.elisanet.fi/oh5fad/ts530/ts530.html#gallery I purchased the new parts kit from Ken at K4EAA. I have a hard time reading or following the schematics for this modular design. Great radio! I would like to get it up & running. Thanks & 73, Peter. KC2RBX

21300. Tuning an SB-200 when driving with a TS-830s or TS-520

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-29 16:21:56 UTC
From: Joe McGerald
Topic: 21300 Message: 21300

OK, this may sound a bit stupid, but I need to ask to keep from frying something.

I have an SB-200 that I generally drive with a S/S rig, so at the moment I don't tune the rig at all.

I would like to drive it with either my TS-830s or my 520. If I tune the 830s with the amp off, then I'm balancing the PI network in the transceiver to the antenna, which is not exactly 50 ohms. Once I turn on the amp, then the xcvr is seeing a 50 ohm load.

What is the proper sequence?

Thanks and 73.
Joe

21301. Question regarding resonant receiving antennas

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-29 18:30:16 UTC
From: James Fogg
Topic: 21301 Message: 21301

I'm new to HF and I use an 80M inverted V antenna and a MFJ Versa Tuner 2 (948) connected to a TS-530S.

I get good results on 80M and OK results on 40M. The higher I go the more deaf my radio becomes. On 20M I hear stations fade in and fade out but they don't stay around long (3 minutes maybe?). I have yet to hear anything on 10M.

My question is should I be looking at aligning my receiver or using a resonant antenna?

Also, in the current propagation climate I don't know what to expect from the higher bands. I've heard people say the are having good luck on 20M.

Hi Joe. You should always tune the transceiver into a 50 ohm dummy load. The amp too. The only on-air tuning you should do is to set an antenna tuner (if you use one). Keep key down times while tuning to 10 seconds or less, and at least 30 seconds in between.

you already answered yourself on this one. your antenna is a 80 meter, no wonder it does not work great on 20, etc

use a resonant antenna or a multiband antenna

21304. Re: Question regarding resonant receiving antennas

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-29 21:59:23 UTC
From: w5rkl
Topic: 21301 Message: 21304

Dave's right. An 80 meter antenna will not perform very well on
20 meters, even with a tuner.

Dipoles are very good antennas for single band operation but not
for multi band operation.

A G5RV will perform quite well as an all band antenna with a tuner.
However, it must be erected properly in order to achieve good
performance. Lack of space, bending the ends down, and wrapping
the 450 ohm stub around a tree, all affect the G5RV's radiation
pattern and it's ability to perform properly. It is true the G5RV's
primary frequency is 20 meters. However, even on 20 meters, if it's
not erected properly, performance will be dramatically reduced.

For multi band operation, especially on 20 and above, a yagi
mounted on a tower or a sturdy pole, mounted at last one half wave
length above ground, is a good choice.

Having said that, one can spend thousands of dollars on antennas
yet be very disappointed in its performance all because the antenna
was not erected properly. In many cases it is not the fault of the
antenna but how the antenna, feed line, grounding, etc, was
installed.

I recommend you take some time and read up on the different types
of antennas. The ARRL Antenna Handbook and/or the ARRL Handbook, both
are usually available at your local library, are excellent sources
of information on antennas, feed lines, and support structures. Also
consider reading up on grounding and lightning protection, all of
which should not be neglected when erecting your antenna.

Try a fan dipole they are easy to make,or a antron 99 will work well on 20 meters with a tuner. A good ground is very important and the higher your antenna the better All of my antennas are flat top,for me they work better than inverted vees AB8WR Marcus

Hello Bob,

This was a while ago but I remember it, and I remember your kind generosity too.

Perhaps you should pop around to Logansport and make sure his house burnt down, if you know what I mean :-)

Jokes aside, I'm saddened to hear of this.

They do say there are three sides to every story - yours, his and the
truth ;-)

Someone suitably near that part of the world could easily lift the phone
and ask this John Acuff what his take on it is, in the interest of
fairness.

Subject: [TS-520_820_530_830] Leaving the group

Well it looks like I will be leaving the group. I lost my barn in a
fire this week in the early morning hours. We think it was a
lightning hit that started it. Anyway, most of my station was in my
shop in the lower level of the barn, including my beloved TS-520S. I
also lost my Yaesu FT-101E and late FT-101ZD, two old tube amps, my
big power supply, several D104 mikes, antenna switch, cantenna, and
my meters and test equipment. In fact the only Kenwood gear I have
left is my TS-700 which I know is OT for this group. I am now HF
radio-less entirely. And of course I also lost a 50 year collection
of tools and shop equipment, three motorcycles, and my wife's car
that I had in the shop to work on. The barn actually belonged to my
aunt, so I had no insurance on the building, and my homeowners won't
cover most of what was there including my ham gear.
I just want to say thanks for having me. I have enjoyed my time here,
and have learned a lot.

I've been looking at fan dipoles from the start. I should have built mine as a fan. I didn't understand the value of resonance for a receiving antenna. Since things like random long wires are used in SWL I assumed that it wasn't critical. Of course, SW broadcasters are using power levels many times greater, too.

are you using open feed or coax?if coax try open feed line if your tuner has place for open balanced line.i love 10m but your not going to hear anything there right now except before a thunder storm.if you need info on ladder line ,do a search or i can provide you place to look.
search for a article"the lure of ladder line".it cannot run alongside metal objects like gutters but can pass by them.....73.....mike
  p.s. if your using coax your losing a lot on tx and rx on 20,15,10 and maybe 40 too if your
inverted v is cut for 80.high swr equals high loss in coax.the tuner makes your rig happy.

Try a fan dipole they are easy to make,or a antron 99 will work well on 20 meters with a tuner. A good ground is very important and the higher your antenna the better All of my antennas are flat top,for me they work better than inverted vees AB8WR Marcus

Topic: 21298 Message: 21315

I think the topic is spot on, and has been handled quite well.

No one likes to be taken advantage of...and it is good that incidences like this one, are discussed publicly, in interest groups like this one.

I always love those few individuals who, if they don't like a subject, try and subject the rest of us to observe their desires to omit, edit, or just plain censor, a topic.

Just a reminder...one does NOT have to read a topic, if they don't wish to do so.

Now...some topics *can* drag out...that is because many people don't read a group on a daily, or even a weekly basis...so they add their comments to a topic that should have died a normal death, many posts past. Or, they have many messages to read each visit tot he computer and even though a topic has been shelved, they don't see any group warning notices until 50 or 100, or 200 messages later. But eventually, even the most visited topic will die, without intervention.

Just my thoughts....

21316. TS820S Poor Tx on LSB

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-05-30 17:10:13 UTC
From: Neil McGrath
Topic: 21316 Message: 21316

I have had my TS820S for a while but have only recently put up an antenna for the lower bands. As I have tried to use LSB for the first time I have noticed that the TX audio sounds tinny compare to USB, when monitored via the headphone jack. There is also some distortion. Not surprisingly I have not had any successful contacts using LSB. USB works fine but does sound like it has slightly too much bass.

Any suggestions on how to adjust the modulation?

Neil
G7AQK

Hello Neil,

My initial thought is the sideband balance adjustment needs attention
and/or CAR1 and CAR2 in the PLL needs attention. These adjustments
are all in the 820's service manual.

Hello all,
I am in the process of setting up my 530 station. It appears that i have some work to do to use the sm 220 on my ts 530sp. Has anyone had any experience with Getting the if conections set up so i can conect to the sm 220. They are not installed from new . I have the paperwork for getting the signal out of my 520 but not the 530sp. It needs 2 one for the v input and one for the pan adaptor. I also think that they are different level signals aswell from reading the 830 book. Also has anyone ever built or adapted another pan adaptor to do the job of the bs-5. Any help is greatly appreciated
Thanks
David VK2DV

The TS-520, TS-520S. and TS-520SE have an IF frequency of
3.395Mhz which is compatible with the BS-5.

The TS-530, TS-820, and TS-830 have an IF frequency of 8.830Mhz which
is compatible with the BS-8.

Unfortunately the BS-5 is not compatible with the TS-530.

Mike,

Thanks for the reply. I had a chance today to take off the TS-830S' covers today and trace the wires of the external connector. Each wire for the relay connects on the external DIN socket terminates to the relay socket correctly. I checked continuity without the relay in place and everything looks good. I didn't see any other wires connected on either the external DIN socket or the relay socket for the contacts used to control an amplifier.

After I buttoned everything up and reconnected the cable I didn't see any continuity on the external DIN connector's relay contacts when keying the transmitter. I'm not sure what's going on. I'll have to take a closure look with the covers off tomorrow. Any ideas?

The problem that I'm having is that whenever I connect the tip of the RCA jack of the relay control to the center conductor of the SB-200's relay jack it keys the amplifier (without making the common shell connection and with no ALC connection). Both the TS-830S and the SB-200 are connected to a common ground using the same method as the TS-820S. I've checked the cable that I bought against the figure in the TS-830S manual and have checked it for continuity and shorts. All seems OK. The cable's DIN connector is connected in the "remote" socket, the one next to the fuse holder.
> >

> > Has anyone else had a similar problem? Any ideas on why I can interface the SB-200 with the TS-820S just fine but not the TS-830S? I'm still suspicious of the cable but wonder if it could be something else.

Hello John,

Since you checked for continuity between the din plug and relay RL1
on the AF Unit, did you also check the relay itself when you had
relay RL1 out of the 830? It is possible relay contacts RL1-2 are
bad and if so will give you the indication you are seeing.

Hi Mike,

The relay being used by the remote DIN connector is the one located under the finals. My plan today is to check it for correct operation.
I will checks its in-circuit operation first and if it is not operating correctly (not closing on TX) I will remove it and attempt to power it from a bench supply.

I tend to agree, Gordon, and I really hope someone does contact him. I don't mean to belabor this topic, but I think I should mention just a couple more points regarding what happened so that all reading this will understand.

I gave this guy plenty of opportunity to follow up with me about the transaction. Before I sent him the rig, he was quite intent to contact me often as to when or if I'd sent it. Once the radio was sent, I'd made several attempts to reach him, still no reply. I made sure he got it by tracking the package online. It was signed for so I know he got it.

I warned him that if I didn't hear back from him, then I was going to warn the group about him. I think I gave him quite enuff time too.

No, I can't speak for him, but I can speak for myself. What he did was not right, and I don't wanna see anybody else get taken by these kind os con artists. They ARE out there.

"Sometimes ya gotta stand up for something, or you'll fall for anything."

Bob

They do say there are three sides to every story - yours, his and the truth ;-)

Someone suitably near that part of the world could easily lift the phone and ask this John Acuff what his take on it is, in the interest of fairness.

Thanks for the advice Mike. I managed to trace TC1 and TC2 on the CAR-1 unit and found that I could adjust them from the underside of the rig (did not even have to remove the covers). They are convieniently labeled USB and LSB. The Tx audio now sounds much better. Thanks for pointing me in the right direction.

As I have tried to use LSB for the first time I have noticed that the TX audio sounds tinny compare to USB, when monitored via the headphone jack. There is also some distortion. Not surprisingly I have not had any successful contacts using LSB. USB works fine but does sound like it has slightly too much bass.

Topic: 21299 Message: 21327

Well maybe I should simplify my question by asking about the polarity of the caps. There is a red wire coming from the rectifier board that connects to a terminal on one of the caps. Does this connect to the + or - side? Then there is a blue jumper that goes between the two caps. What terminal does it connect to? Then there is a green wire that comes from the transformer and goes to the second cap. Does this attach to the + or - side of the second cap? From the pictures it appears that they may be wired in a series but I am not certain. Any help would be welcome. Thanks, Peter. KC2RBX

21328. Re: Capacitor Replacement on TS-530s C23 & C24

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-01 14:09:12 UTC
From: w5rkl
Topic: 21299 Message: 21328

Hello Peter,

The RED wire from the Rectifier board connects to the "Positive" (+) terminal of C24. The blue jumper wire connects from the "Negative" (-) terminal of C24 to the "Positive" (+) terminal of C22. The Green wire from the transformer can connect to either the "Positive" terminal of C22 OR the negative terminal of C24. Make sure the GREEN wire from the transformer actually originates from the transformer's "0" terminal on the 800 volt secondary. Last, a wire should connect from the "Negative" terminal of C22 to chassis ground.

Each capacitor should have a 470K 1/2 watt resistor and a .001ufd 500VDC disc capacitors connected between the "Positive" and "Negative" terminals of each capacitor. The resistors act as "equalizing" AND "bleeder" resistors. Do NOT forget to connect these components across each capacitor.

The RED wire should originate from the Rectifier board's "800" terminal and the GREEN wire should originate from the transformer 800 winding's "0" terminal.

If all this doesn't make sense, is difficult to understand, and reading the schematic is difficult to you, then may I recommend finding a local ham who understands this to help you. If you connect the capacitor's up incorrectly, wrong polarity, etc, you can easily cause permanent damage to the power transformer, the Rectifier board, and yourself. The voltages, both AC and DC, inside the 530 can kill so don't try it yourself if you are not sure of what you are doing. Find some help.

From: Mike Rodgers
Topic: 21301 Message: 21329

you should be hearing activity on 20,even with a non resonant antenna in daylight hours. sugest a fan dipole.if your going to buy one,they're not cheap and they're not perfect solutions.you could put up a seperate wire for 20..32.75 feet long(468 divided by frequency).
check the website hamuniverse.com i still think you should think about feeding your dipole with open wire feed if your tuner can accept it.you can read all about that in the arrl handbook as well.coax has a lot of loss at high swr and open wire has very little.when your trying to use a 80m wire on 20 there is very high swr between the tuner and antenna. there are articles at hamuniverse.com for building fan dipoles if you want to do that...mike

Dave's right. An 80 meter antenna will not perform very well on
20 meters, even with a tuner.

Dipoles are very good antennas for single band operation but not
for multi band operation.

A G5RV will perform quite well as an all band antenna with a tuner.
However, it must be erected properly in order to achieve good
performance. Lack of space, bending the ends down, and wrapping
the 450 ohm stub around a tree, all affect the G5RV's radiation
pattern and it's ability to perform properly. It is true the G5RV's
primary frequency is 20 meters. However, even on 20 meters, if it's
not erected properly, performance will be dramatically reduced.

For multi band operation, especially on 20 and above, a yagi
mounted on a tower or a sturdy pole, mounted at last one half wave
length above ground, is a good choice.

Having said that, one can spend thousands of dollars on antennas
yet be very disappointed in its performance all because the antenna
was not erected properly. In many cases it is not the fault of the
antenna but how the antenna, feed line, grounding, etc, was
installed.

I recommend you take some time and read up on the different types
of antennas. The ARRL Antenna Handbook and/or the ARRL Handbook, both
are usually available at your local library, are excellent sources

of information on antennas, feed lines, and support structures. Also
consider reading up on grounding and lightning protection, all of
which should not be neglected when erecting your antenna.

I acquired an extra TS-830s over the weekend, and I don't need two of them. I have checked it out on CW during the DX contest and used it to check into a net last night on 75M. Its very clean and seems to work perfectly.

I'm open to selling it or taking something in trade or partial trade. If you are looking for a clean TS-830s please contact me via email.

Thanks and 73.
Joe

I finally did get things working yesterday. The relay coil was functioning properly (pulling closed on TX) but the contacts on the relay were dirty. I used a business card to clean up the contacts and I started seeing continuity between the two pins on the remote DIN connector during transmit. I connected the control cable (relay side only) and I'm able to use the SB-200 with my TS-830S. I haven't tried connecting the ALC side yet.

When inspecting the relay contacts I did notice that the contacts seemed slightly pitted which makes me think that I should look for a replacement. Anybody have a source for a replacement for this relay? It's an OMRON MX2P 12VDC. This relay is the T/R relay that is located under the finals and is covered by a metal enclosure.

From: w5rkl
Topic: 21288 Message: 21333

Congratulations Jon, glad to hear you got it working.

Check K4EAA's website, www.k4eaa.com as he may have the relay
you need.

As for relay pitting, this can happen over time when switching
voltage. In some cases when high voltage is switched through the
relay contacts. Every time there is a spark when the relay contacts
make and break connection, the spark creates carbon deposits on
the relay contacts. If this continues over a long period of time,
pitting and increased carbon build up occurs on the relay
contacts. If the voltage that is switched by the relay contacts is
high, such as in an unmodified SB-200 or SB-201 amplifier, then
pitting and carbon build up occurs rather quickly.

I don't recall whether your SB-200 has the soft key mod or not. If it
does not then the SB-200's full high relay voltage will be
applied across the 830's relay contacts. There are hams who key their
SB-200 and SB-201 using the 830 or other hybrid relay contacts
but, I don't recommend it.

IF your SB-200 does not have the soft key mod installed, I high
recommend installing it or using a ready built, or build one
yourself, amplifier keying interface.

The bottom line here, Jon, is it's up to you which route you take.

21335. TS-830S RF Output suddenly gone

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-01 23:13:59 UTC
From: rdmegargle
Topic: 21335 Message: 21335

TS-830S. My power out is suddenly only a few watts and no ALC action from the driver. Carrier control has no effect. I performed the following measurements with a DVM (all units are VDC):
V1
Pin 1 stby 0; TX 0
Pin 2 stby -43.5; Tx 0.4
Pin 7 stby 338; Tx 329
Pin 8 stby 248; Tx 242

Finals
Pins 1, 4, 6 stby 0; Tx 1.36
Pin 3 stby 254/254; Tx 243/243
Pin 5 stby -100/-100; Tx-60/-60

Rectifier Unit
300B 336
210A 255
210B 257

On Tx, V1 Pin 1 cathode voltage of zero is a problem. Pin 7 and 8 seem off normal readings in Tx as well.

Any suggestions? Any other places to check? What could be causing the no cathode voltage on transmit at V1?

Russ

Hello Russ,

The final tubes are wired in parallel which means the cathode voltage on V1 and V2 is the same. A change in the cathode voltage, zero as you have indicated, indicates a failure of one or more of these resistors. I recommend changing all 4 of these resistor with new 20 ohm 1/2 watt resistors. You can get new resistors at Mouser Electronics, www.mouser.com or your favorite online or parts store.

21339. TS-820 RF Proc.

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-02 16:23:37 UTC
From: jsloss
Topic: 21339 Message: 21339

What is the correct frequency for the 455 KC oscillator. I recall a while back a comment that the frequency in the service manual was incorrect.

I've noticed a very slight audio distortion on the first few syllables of incoming speech. Signal strength of the received station does not seem to be a factor.

Your thoughts will be appreciated.

My mistake Russ, I confused your question with the final tubes.

Anyway, as I mentioned in my e-mail response, since most of the voltages on the driver tube are close to what they normally should be but the cathode voltage is 0 in both transmit and receive, then I suspect a bad driver tube. I didn't mention this in my e-mail response, but check L38, R35, and R41 in the driver tube's cathode circuit. If L38 is open then there will be no cathode voltage resulting in no voltage on the cathode of the driver tube in standby and transmit.

ALC is produced by grid current flowing in the final tubes, not the driver. When the grids of the final tubes become positive, based on the level of RF signal from the driver tube, current flows between the both final tube's cathode and grid. The positive voltage created by the grid current flowing in the final tubes is sensed by the ALC circuit on the AF Unit and the ALC circuit produces the ALC voltage that is fed back to the IF Unit to control the gain of Q29.

I still recommend checking the final tube's cathode resistors, R2 thru R5 and if they have changed values, possibly due to age etc, replace all 4 of them with new 20 ohm 1/2 watt resistors.

Jim,
Try cleaning/lubricating the ends of the main tuning condenser. I've used
CAIG De-Ox on those I've found and it has seemed to do the trick.

21343. FS: Kenwood KB 1 Deluxe Tuning Knob

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-04 05:56:09 UTC
From: dr7zyq
Topic: 21343 Message: 21343

I am selling my like new KB-1 deluxe tuning knob for the TS-830S transceiver. I believe it will work fine with other rigs of that vintage but only present it for the TS-830S because that is the rig it was sold for.

I am the original owner and only installed it to see what it looked like, then removed it, put it away and forgot about it. Hence, it is like new, in the original little box with the original instruction sheet and allen wrench for removing and installing the tuning knobs.

$100.00 including shipping within ConUS. Payment by USPS postal money order only.

Thanks,

David, WA7ZYQ
north Idaho

There is no "correct" frequency. The best way to align the processor is to monitor the processor output with a scope and adjust the oscillator frequency for a peak audio output with least distortion with proper input level. The crystal filter passband characteristics vary from filter to filter, and AGE. Once you adjust the frequency for best performance, make a lablel and put the measured frequency on the xtal filter for future alignment reference.

Topic: 21346 Message: 21346

I replaced my radio's desk with a different one early last week. Everything seemed fine. I tested the radio after it was put back together and it worked fine. However, when I tried to get on a couple days later I could barely bring in 20meter. When I moved to 75 meter (where I normally have it), I could only hear static. Tried back on 20m and same, even when I tried to listen to some CW. I thought maybe the driver. Replaced and that wasn't it (was told it wouldn't have been the driver anyways). My paperclip jumper is still on the back. The cables are still firmly in place. I dont' think it was hit by lightening (I figure I would know if it was then again maybe not). A friend is going to take a look at it tomorrow but I thought I would see if there are any ideas today? It sounds about the same as when I first got it. I will be spraying some more cleaner inside that's safe for it (forgot what it's called ; got it from Radio Shack;
have it at home) to see if that helps.

I miss the contacts...

Hi Guys. When using DeOxit inside the VFO, be very careful to use
only a very tiny amount, and make sure none gets on the circuit board!

Date: 2009-06-04 15:02:21 UTC
From: kb6ltych
Topic: 21349 Message: 21349

hello to all,
sorry if this was addressed in previous discussion, I tried to search for but could not find.
our 520 has been working just fine, when yesterday it was turned on the meter instantly went to max deflection. after some dialing around it went back to normal, but it has done it again today.
is this a ground problem?

Thanks
Christy KB6LTY

Hello Christy,

Have you tried cleaning the RF gain control with contact cleaner then rotating the RF gain control throughout its travel a few times?

Hello Angie,

First, neither the driver tube or the final tubes have anything to do with the receiver.Changing them will not fix the problem.

I suspect dirty relay contacts. I recommend pulling the relay and cleaning the contacts with contact cleaner and a thin piece of paper.

While you are at it, I also recommend cleaning the wafer switches with contact cleaner as well. Do not over do it with contact cleaner. A little goes a long way. Use canned air, after cleaning the relay and wafer switches, to remove excess contact cleaner then wait 3 to 5 minutes before powering up the radio.

21352. 820S IF Board

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-04 23:05:03 UTC
From: jsloss
Topic: 21352 Message: 21352

Problem board has very weak calibrator receive and no ALC, Ip, or PO (w/ CAR control full CW) but everything works just fine on USB/LSB.

Problem confirmed in IF board by swapping w/ known good board.

Would appreciate hints as to where to start looking from those who have been there and done that.

Mike and gang,
I was able to get the 820S back on the bench today. I found the problem. VR1 on the Carrier board was way out of adjustment. I adjusted it so the USB and LSB carriers are equal. Now the carrier suppression adjusts perfectly. Both USB and LSB are now equal to a mv.
Just need to pick up a good pair of 6146B's and I'll have this radio ready to sell.
Thanks for all the tips Mike.
73 to all.
Gordon

Correction to my last:

Weak (S 0 or less) calibrator signal w/ mode switch in TUNE or CW and SEND/RCVE on receive. USB/LSB reception just fine.

Whatever is happening the rig works fine in USB/LSB but not in TUNE or CW modes. Problem is in IF board.

Hi Angie,

Please remove and install the jumper paperclip,
sometimes that connection gets dirty and no receive,
just static.

You may want to check the plastic shaft couplers,
they may need to be replaced.

use a business card, trim it with scissors,
a drop or two of DeOxit to clean the relay contacts.
they are very delicate, go slow and you'll do fine.

Let us know what you find.

Ken,
I did move off VFO to 25KHZ, and same static. It doesn't bring in, what I call, the "test" signal.

Angie,

Can it hear the calibrator signal?

Mike,

I know the drivers weren't the culprit (I didn't think they were but I wanted to try anyways and a friend also confirmed they wouldn't do anything). :)
I also thought of the cleaner (which I mentioned in the previous email). I used the Deoxit cleaner just over a year ago to clean the wafers and such. I definitely agree a little goes a long way. I just wish it would have gone longer. :) I just didn't get a chance to use DeOxit this morning but I brought it with me to give to my friend along with the radio.

I also checked the antenna outside and it is still up so that was a relief.

I appreciate everyone's help and glad I thought of the same things others have.

Hope everyone's having a good week.

Hello Angie,

First, neither the driver tube or the final tubes have anything to do with the receiver.Changing them will not fix the problem.

I suspect dirty relay contacts. I recommend pulling the relay and cleaning the contacts with contact cleaner and a thin piece of paper.

While you are at it, I also recommend cleaning the wafer switches with contact cleaner as well. Do not over do it with contact cleaner. A little goes a long way. Use canned air, after cleaning the relay and wafer switches, to remove excess contact cleaner then wait 3 to 5 minutes before powering up the radio.

Hello Christy,

Have you tried cleaning the RF gain control with contact cleaner then rotating the RF gain control throughout its travel a few times?

Hi,

Please contact me off list if you would like a pair.

ONE PAIR each:

NEW Panasonic 150uf 500WVDC electrolytic caps *
NEW bypass caps and
NEW 1W bleeder resistors.

* 35mm in diameter, fits existing clamps perfectly.
USA Made in TN by Panasonic.

Paypal, Postal or Walmart money orders just fine with me.

$ 25.00 shipped Priority US Mail with tracking !

Need more then one pair ?
$ 20.00 for additional pairs shipped to same address.

21361. Perplexing TS-820S Problem

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-06 19:44:16 UTC
From: Steve
Topic: 21361 Message: 21361

Hello,

I have a perplexing TS-820S problem I would like to share in hopes that someone might have an idea as to what may be causing it. On 160 thru 15 meters, the frequency display is solid after warm up. However on ten meters, the frequency display jumps all over the place. Below are some examples:

Band Switch = 28
Mode Switch = LSB, USB, or CW
Set frequency via vfo to 28.350.0
Frequency display fluctuates between 28.349.8 and 28.350.4

Band Switch = 28.5
Mode Switch = LSB, USB, or CW
Set frequency via vfo to 28.850.0
Frequency display fluctuates between 28.849.0 and 28.851.0

Band Switch = 29.0
Mode Switch = LSB, USB, or CW
Here it is really wild, tuning the VFO has little effect and the frequency is jumping all over, from 28.990.0 to 29.100.0.

On power up, sometimes with the band switch in the 29.0 position, the display reads in the 24.xxx.x range, then after about 5 minutes goes to the correct frequency.

Band Switch = 29.5
Mode Switch = LSB, USB, or CW
Set frequency via vfo to 29.850
Frequency display fluctuates between 29.849.8 and 29.850.7

The radio was like this when I received it, and the previous owner says he never operated on 10 meters so was unaware of the problem.

My troubleshooting and repair skills are at a beginner level with some experience (replacing filter capacitors, finding and replacing burnt components, etc).

Any thoughts on how to solve this problem would be appreciated. This is really a nice looking TS-820S and I would love to get it working right!

Thanks,

Steve K7QHU

You've probably got some dirty contacts connected with the 10m switch positions (my 830s is solid from the instant you turn it on - so dirty contacts would be my first starting point)

Hello, I have received a Kenwood TS-830S with some form of cannibalism ... without 12BY7 driver tube and with 2x S2001A final tubes.

In RX it's OK, removed some 'home made mods / bridge' (this radio was used with some datong audio processing or similar...) and now it sound good...

I have TX with this radio without his driver tube (I didn't know); could be a problem? S2001A are 6146B compatible?

I have 'ebayed' and waiting for a 12BY7 and 2x 6146B tubes; what can I test / measure before to replace these tubes?

The RF unit and the Final unit seem to be original...

Well, the question is - how much RF, and on what frequency?

With the lid off and the PA valves out, I could pick up my TS-520 for a good 30 feet or so.

It's also possible that the PA is oscillating at some weird frequency, and that is causing the RF deflection on the meter (if you get any).

Take nothing for granted, and follow the neutralising instructions carefully when you get your new valves.

Gordon

21365. Missing tubes

21366. Re: Perplexing TS-820S Problem

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-08 18:34:03 UTC
From: w5rkl
Topic: 21361 Message: 21366

My first suggestion is to check the AF AVR UNIT board's 3.3VDC and 9VDC. Over time along with aging components, these 2 volts can easily change, increase or decrease.

The AF AVR UNIT board is located on the bottom of the 820, directly below the VFO. There are "3" plugs, 2 six pin plugs on the front of the board and one 11 pin plug on the rear of the board.

Remove the top and bottom cabinet housing then turn the 820 upside down with the front panel facing you. The AF AVR UNIT board is directly behind the front panel and directly below the VFO.

The 3 plugs are as follows:

AF1 - Left plug, close to the front panel
AF2 - Right plug, again like the AF1, close to the front panel
AF3 - on the rear of the board.

AF1 and AF2 plug numbering goes from right to left, 1 thru 6.

Adjusting the 3.3VDC and 9VDC required adjusting 2 small vertically mounted pots, VR1 and VR4. VR1 is located between AF1 and AF2. VR4 is located approximately in the middle of the board. There is a "light colored" pot located to the right rear, do not adjust this pot! Leave it alone.

Connect a DC volt meter to AF1 pin 1. The voltage should be close to 9VDC. If the voltage is lower or higher than 9VDC, adjust "VR4" so the meter reads 9VDC +/- .1VDC.

Now, move the meter's positive lead from AF1 pin 1 to AF2 pin 6. The voltage should measure approximately 3.3VDC, +/- .1VDC. If the voltage is not 3.3VDC, adjust VR1 so the meter displays 3.3VDC.

Allow the 820 to warm up for approximately "30 minutes" before attempting to measure and, if necessary, adjust these two voltages.

Next, spray some contact cleaner on the Band Switch wafers and the Function Switch. Rotate each switch through out their travels a few times. Use canned air to remove any excess contact cleaner. Wait 3 to 5 minutes before powering up the 820. Use only small amounts of contact cleaner, do NOT soak the switch wafers. Always use canned air to remove any excess contact cleaner.

Next, turn the 820 right side up, front panel facing you. The VFO is in the front middle of the chassis. Look on the right side of the VFO and you will see a small metal plate with 2 small phillips head screws. Remove one of the screws, rear screw is easiest to remove. Swing the plate upward so you can see the VFO's variable capacitor. Rotate the VFO to the top of the band. Look inside the square hole on the side of the VFO. You will notice the variable capacitor shaft has a "Fork" like device with the capacitor's shaft in the middle of the fork. Spray contact cleaner on this and rotate the VFO throughout it's travel a number of times. Again, with contact cleaner, remove excess contact cleaner. Also, again,

use just enough contact cleaner to remove any dirt or corrosion. Again, wait 3 to 5 minutes before applying power to the 820.

Now, reconnect all cables and power up the 820. Check each band for stability in the VFO. If all is well, turn on the calibrator, MARKER 25Khz setting on the FUNCTION switch, and tune the VFO to an even 00, or 100 interval on the dial. You should hear the MARKER signal. Adjust the DRIVE control for maximum meter display, in receive. Look at the digital display and the main analog dial, they should be very close to being either 0 or x.100 etc. If they are not, hold the round plastic ring behind the main tuning knob steady while rotating the main tuning knob so the digital display and main dial read even 0, x.100, etc, as you tune the VFO. The digital display should display the frequency of the main tuning dial, or very close to it.

If all is well then you have fixed your problem. If not, then turn power off, wait a few minutes for the power supplies to discharge to zero and remove all cables. Turn the 820 upside down and carefully, remove each plastic plug on each board, clean the pins with contact cleaner, and reinstall the plug. Do each plug individually so you do not loose track of where the plugs go. The "IF" board has quite a few plug and each one must be installed correctly, especially the filter selection plug, the next to last 3 wire plug. Installing this plug incorrectly can prevent the proper selection of the sideband and CW filter, if the CW filter is installed. See the 820's operating manual on how to install this plug. The DG-1, digital display unit, has "3" connections, one on the bottom of the Unit (under the chassis), one to the digital display tube, and one to the 5VDC supply, small PC board mounted on 2 metal stand off, between the rear of the IF board and the power transformer. Clean all 3 of the connectors, one at a time, and reinstall the plugs.

If the problem is still there, you will most likely have to remove the PLL UNIT assembly, remove the CAR1 and CAR2 boards inside the metal enclosure, and separate the two boards. Clean the pins that connect the 2 boards together, and reiconnect the 2 boards together and mount the boards in the metal enclosure and reinstall the PLL unit and reconnect the plugs to the PLL UNIT.

Check all PC board mounting screws to ensure they are tight. If necessary, loosen each screw 1 full turn then tighten the screw.

The relay contacts on the RELAY UNIT can become dirty with carbon build up which increases resistance through the relay contacts. The receiver's AGC voltage flows through the relay mounted on the RELAY UNIT, on the bottom in the middle of the chassis. If the contacts become dirty with carbon, the plastic cover must be removed. This is not easy but, with patients, you can remove it without breaking the plastic cover. Use contact cleaner on a piece of paper, slid between the contacts a number of times then use canned air to remove any excess contact cleaner. You may have to do this a few times but it's worth the trouble. The antenna change over relay contacts, located on the bottom and to the rear of the final unit, can also become a problem, especially with weak or intermittent receive sensitivity. The MARKER signal may appear to be strong but incoming signals may appear to be weak, carbon build up on the T/R relay. To remove this relay, remove the 2 screws holding the SG switch to the rear panel, pulling the SG switch gently forward. Now, remove the 2 screws that hold the T/R relay metal cover. Locate the 2 screws as they may fall down onto the chassis and may roll under the final unit. Do the same thing, remove the plastic outer covering and clean each relay contact with contact cleaner, being careful not to bend or twist the contacts. Clean each bottom plug in pin with a brush and contact clenaer. Remove any excessive contact cleaner with canned air and reinstall the relay. Be careful not to

bend any of the relay plug in pins.

Again, age and dirt/corrosion/carbon build up can cause all kinds of problems. Take your time and be careful removing and installing the plugs and relays. Check to see if the problem has been eliminated.

Sorry for being long.

73
Mike

From: Kevin King
Topic: 21367 Message: 21367

Folks,

Please search your parts drawers, I am looking for a fundamental xtal at or about 14.135 mhz.

Thought I would check before I had one cut.

-Kevin

12BY7A received, but it doesn' work. Now I checked some others connection and... the violet/white wire from SG pin in the Final Unit to PD2 pin in the Rectifier Unit is disconnected... why this?

Maybe this radio has some other problem? Or maybe this OM was not authorised to transmit?

This evening I connect newly this wire as original...

Just put up my Hustler 4btv and several HF receivers display all dots or all
or some bands. Is it related to the antenna installation or just everything
broke at once?

I recommend testing the final tubes before applying power. I say this since you are not the original owner and you have no idea what condition the final tubes are in. Naturally, replace the driver tube with a known good 12BY7.

Inexpensive tube testers cannot test a tube in an RF environment. Most inexpensive tube testers can only test for shorted/open filaments, shorted elements (grid shorted to cathode, screen shorted to grid, etc), and simple conduction, nothing more. If you find one or both final tubes to be weak (conduction) or shorted, replace both of them. You do NOT have to purchase expensive "matched pairs"! That's a waste of money and you will not realize any improved performance with matched tubes over unmatched tubes!

When testing tubes, let the tube warm up for 5 to 10 minutes in the tester before testing. If any element will short due to heating the inside of the glass envelope, the 5 to 10 minute warm up period will aid in discovering heat related shorts in tubes. I have experienced 6146 tubes that test "good", no shorts, when allowed to warm up for only 2 or 3 minutes. However, allowing the tube to continue to warm up for an additional period of time, the tester indicated the tube was shorted.

I also recommend checking the final tube's cathode resistors, R2 thru R5, on the final amplifier PC board. You have turn the 830 upside down to locate the cathode resistors. Each one is 20 ohm at 1/2 watt. If one or more of these resistor indicate they are damaged or have changed resistance outside of the 10% tolerance, change all 4 of them with new 20 ohm 1/2 watt resistors.

If you end up replacing the finals, I strongly recommend neutralizing the final amplifiers. The final amplifier neutralizing procedure is covered in both, operating and service manuals for the 830. If you do not have either manual, you can download them from N6WK's website.

http://www.n6wk.com/kenwood/

I recommend you obtain these manuals, if you do not already have them, when servicing AND operating the 830.

The antenna has nothing to do with failures of the receivers digital displays.

Since you didn't state what make and model of receivers you are using, providing suggestions to track down the source of the problem is not possible.

Also the red wire AC800 on Rectifier Unit was disconnected.

Now, on USB Mode I go on TX, Meter Switch on Ip; I read about 60 mA (corrected with Bias rear control). With Meter Switch on HV it's possibile to read about 900V.
On my second receiver I listen a tone, also without microphone connected to the TS830.

On Tune MODE, with Meter Switch on ALC or RF I don't read anything.

uffffff

Any Idea? Another wire disconnected?

Sorry about that!! It happened on my kenwood ts-440s, ts-180s and my
ts-940s at the same time. Working fine a week ago and then on the
newly-installed Hustler all 3 units went dots on me.
thanks
Robert

21375. TS-520SE transmit alignment help needed

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-10 00:10:07 UTC
From: Herb
Topic: 21375 Message: 21375

Hey all,
My name is Herb and my call is KC5MO. I have aquired a TS-520SE from a coworker and got the adjsutments done on the MIX,ANT and DRIVE. The only thing left is to get it on frequency. So far 20 meters is spot on, but 160, 80 and 40 meters are off. Before I start tuning the OSC coils I figured I had better get some advice on getting the TX frequency aligned from some experts. All help/tips are greatly appriciated.

Thanks
Herb KC5MO

21376. Microphone for TS-820S

I haven't been on SSB for 10 years. I'm a CW addict, but now I want to play with my TS-820S on SSB. The ham I bought it from included a nice Electro-Voice 638, but the specs on that model say "sensitiviy rating -153db" and the Kenwood manual says I must have a mike with sensitivity rating in the range of -50 to -60 or it won't work right. I would appreciate any recommendations for an affordable used mike I can use with my rig.

Thanks for your time and recommendations.

73,

The only really important thing is the mike impedance. A low impedance mike won't really work with the TS-820 (or any other of the TS-[58][23]0 family) without a preamp. You need a high impedance mike, which typically has a little matching transformer in it. Many base-station mikes have a way of switching between high and low impedance, either with an actual switch or a reversible plug.

The first picture I found of an Electro-Voice 638 says "IMPEDANCE HI-Z" on the back, so that should be fine.

If you use a low-impedance mike on your TS-820, nothing bad will happen. You'll just sound quiet and muffled. At a pinch you could use a low-impedance mike and shout, if you were (for example) stuck on a desert island with a TS-520 and the wrong mike.

When I got my TS520S from eBay it had no mike,
the only mike I had available was a low impedance (magnetic) desk microphone, so I tried it.
No problems making DX conacts etc.
So if you have any mic try it !
Sulaiman

P.S. I have to turn mic-gain to full so there may be some audio hiss, but compared to ssb noise probably insignificant.

There are any number of simple mike preamp/filter/processor circuits out
there on that there Intarwebs. Pretty much all of them work, it's not
really something you can get wrong.

Any preamp with more than two transistors is more complicated than you
need for this ;-)

I appreciate all your help. The manual is VERY specific in saying the sensitivity MUST be between -50 and -60, or the rig won't work right. Also, I talked with Heil Sound and Bob Heil said the TS-820S is the rig he used to develop his HM-5 mike element and that should work perfectly. Unfortunately, it costs $70 for just the element. They (Heil) also suggested I look for a used Heil Classic which should do nicely. I guess I'll take the cowards way out and stay on CW a little longer. Thanks again, folks.

Good Afternoon:

My TS-820S has an IF output on its back panel. Can I run the output directly into the SM-220 IF input?

I understand that the TS-830S series could... but was lead to believe that the TS-820S couldn't without a modification from the BS-8 out.

PS: I'm a new member of the group... glad I found you folks.

The TS-520 manual makes no mention of "sensitivity" for the microphone,
only that it needs to be 50k impedance. I don't really see how you
could have a useful measurement of sensitivity here.

Like I said previously, just about anything with a high-impedance output
or a preamp will work. There's no great mystery to it.

Gordon

James,
I got the radio back on Monday. The Elmer couldn't find anything (see I figured it was the user, aka ME LOL). He did replace the paperclip jumper by creating the plug for it, so maybe that's why it works again? I might get on tomorrow night to see how it goes.

Thanks for the suggestion.

Hi Angie,

Please remove and install the jumper paperclip,
sometimes that connection gets dirty and no receive,
just static.

You may want to check the plastic shaft couplers,
they may need to be replaced.

use a business card, trim it with scissors,
a drop or two of DeOxit to clean the relay contacts.
they are very delicate, go slow and you'll do fine.

Let us know what you find.

73 james ke4dɾn

I must admit to getting more than a bit frustrated with the technical
demise of the average Ham.

take the above
"but the specs on that model say "sensitiviy rating -153db"
dB relative to what ?
a millivolt
a microvolt
a volt
a milliwatt into 600 ohms
a milliwatt in to 50 ohms

Come on guys a dB is a logarithmic unit of the ratio between two levels.
It takes a lot to overload the first stage of the Mic amp, and should
it be to high there's a knob on the front "Mic GaiN" which can be
adjusted.
I guess Mike W5RKL must read some of the questions asked with
disbelieve at the low level of of understanding of very basic
electronics. But I give him a lot of credit for always answering and
being helpful.
I know technical requisite levels have dropped in the UK for gaining a
licence, but what's happened in the USA ?

One of the reasons Hams are recruited by electronics companies is their
resourcefulness, their ability to be able to often misuse equipment to
make it do what they want it to.

Whats happened to the plug it in and see if it works, or have we gone totally mad with Health & Safety regulations needing training and a certificate before plugging it in.

If I'm the only person who feels this way I'll leave the list. But I'd prefer to stay just in case someone asks a question I can help with, I must have learnt a few things in the last forty odd years I've been working with RF.

--
Best wishes

21388. Newly Aquired TS-520S

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-10 22:31:46 UTC
From: Gmail - Kevin, Natalia, Stacey & Rochelle
Topic: 21388 Message: 21388

HI All,

Just aquired a TS-520S in good condition for it's age.

Has a good RX and TX is excellent with 130 watts into a matched antenna and dummy load.

However a couple of minor issues I would like to fix
1. the VOX switch is broken, is there replacement swtiches to fix?
2. The mic was lost from the owner and replaced with a GE CB mic. The impedenace are the same, just would be nice to have a Kenwood mic.

Not much else to know about this radio, need to get it on the desk and fully look it over and try it out.

Regards

Kevin, ZL1KFM.

Almost any crystal mike such as the D104 should work. I've been using a $1.49 replacement crystal cartridge from the long gone Lafayette Radio since my Heathkit DX40 days and now on my TS530s with good reports all these years.

Good luck and have fun

I appreciate all your help. The manual is VERY specific in saying the sensitivity MUST be between -50 and -60, or the rig won't work right. Also, I talked with Heil Sound and Bob Heil said the TS-820S is the rig he used to develop his HM-5 mike element and that should work perfectly. Unfortunately, it costs $70 for just the element. They (Heil) also suggested I look for a used Heil Classic which should do nicely. I guess I'll take the cowards way out and stay on CW a little longer. Thanks again, folks.

I've been watching this thread for a while now.

Just to answer Karl's question: I used and EV638 on one of my TS-520's for a couple of years. Got great audio reports. Did not have to use anymore audio gain than I did with an old MC-50. Matter of fact, I have a 520 on the bench now, and will probably use the 638 on it when the repairs are finished.

Just my opinion, but it worked with no problems at all.

Have a nice day es 73,

The switches are (as far as I've seen) only available from people
parting out other TS-[58][23]0 radios. The two most common mikes seem
to be the Kenwood MC-50 desk mike and the MC-10 fist mike. I use the
latter, because I just don't have room for a desk mike. Both crop up on
eBay from time to time.

It's often useful to steer people in the direction of the "Smart Questions" FAQ, even if it is more orientated towards computers - http://catb.org/esr/faqs/smart-questions.html
Quite often people ask "stupid" questions because they don't quite know how to frame the question accurately. Once you've found the right question, it often answers itself.

One of the great things about amateur radio is that everyone has a different field of interest and expertise, so you can generally find *someone* who has the knowledge or bits that you need. Quite often the bit of knowledge that people need is obvious to you but totally counter-intuitive to them!

I agree with Richard's point about people just not trying stuff any more. That's one of the reasons I stopped hanging about in ##electronics on Freenode - you can get tired of explaining why you don't get 23.74 ohm resistors for running LEDs off 5V supplies, and why you don't need them. The electronic music fora and lists are much the same - people get bogged down in detail but never plug in the iron. Or mike, or morse key, or whatever else.

Heigh-ho, I suppose the less time I spend in front of the computer railing against ignorance, the more time I have to brush up my CW.

Hi Karl. First of all, Heil products are very overpriced, and in my opinion do not sound any better than other mics. Of course Bob Heil is only going to recommend Heil products. The Electro-Voice 638 mic should work fine. You could also find an MC-50, or a Sure 444, as both are commonly used on many older radios. These older Kenwoods sound good with almost any microphone you can find. I have used hand mics that came from junked CB radios (impedance unknown)on my TS-530S, and the TS-520 I had years ago with good reports.

The standard CB hand mic will require some re-wiring inside the mic. Most amplified mics had a switch. You do have to be careful with amplified mics though. If not set properly, they will pick up every little sound. In many cases you will need a quiet room when using an amplified mic.

This group and others like it are here so that the more knowledgeable folks can help those who need help, and share their experiences.

If you connect the IF OUT on the back of your TS-820S to the V. INPUT on
the lower left
front panel of the SM-220, you should get a pattern on the scope screen
when receiving. If the
BS-8 pan adaptor is installed inside the scope, the band scope function
will function also.

An unmodified TS-820 does NOT have an IF out connection on the rear
panel.

The 2 female RCA sockets on the rear panel, between the fan plug and
the SG switch, are for connecting the X-Verter "IN" and "OUT"
connections. Neither of these sockets provide an IF signal.

The 2 female RCA sockets located below the 8 pin octal socket
provide transmit and receive "Audio" connections for external
"audio" devices such as a phone patch, computer sound card interface,
etc. Again, neither of these socket provide an IF signal.

The step by step modification instructions are covered in the SM-220
operator's manual on page 16.

If you do not have the SM-220 and the TS-820 manuals, you can download
them free at the following links.

SM-220 manual link:

http://www.radioamateur.eu/schemi/Kenwood_SM220_user.pdf

TS-820 manual link:

http://www.kenwoodusa.com/Support/Amateur_Radio/#_

Simply scroll down to the manual portion, click the drop down
menu, and select TS-820S. When the download link appears, click the
link and download the manual.

Martin wrote:
"> Most amplified mics had a switch. You do have to be careful with amplified mics though. If not set properly, they will pick up every little sound."

Martin is correct but there is another problem that is associated with amplified microphones.

Quite often, users of amplified microphone do not adjust the radio and the microphone gain controls properly. An improperly set MIC gain and amplified microphone gain control, can easily create distortion which results in splatter.

Here's a easy procedure to properly set both gain controls, the radio's MIC gain and the amplified microphone's gain control.

Plug a non-amplified microphone into the radio. Set the meter to ALC, connect the radio to a dummy load, then press the PTT button. While speaking into the microphone in a normal voice, adjust the MIC gain for a peak ALC meter reading that does not exceed the ALC scale.

Next, connect the amplified microphone to the radio. Set the amplified microphone's gain control to minimum, set the radio's meter to ALC, but do NOT adjust the radio's MIC gain setting! Again, while speaking into the microphone in a normal voice, adjust the microphone's gain control so the peak ALC meter indications are "slightly" less than the non-amplified ALC meter peaks. Ensure to turn the radio's speech processing "OFF" when using an amplified microphone!

If reports of distortion, splatter, or other abnormal audio are received while using an amplified microphone, cease using the amplified microphone. Determine the source of the distortion and eliminate it before using the amplified microphone again.

Knowingly using a microphone that produces distortion which results in splatter to adjacent frequencies above and below the operating frequency is a violation of part 97 of the FCC rules and regulations and is defined as "intentional interference!"

Mike,
I have 2 UNmodified 820's here and they BOTH have the IF out on the back.
When looking at the rig from the rear, they are in the upper right corner.
The label is hard stamped into the back panel from the factory.

On my TS-520S, my main dial is out of calibration with the 25 KHz marker and with WWV. How do I get it into calibration? Is that a VFO adjustment? Any advice would be appreciated.
73s, Scott, N6CIC

Topic: 21376 Message: 21403

Hey, folks, I certainly didn't mean to start any heated discussion about microphones or even my intelligence. (The latter has ALWAYS been in question.) But I seem to have peeked the ire of at least one of my fellow hams. I apologize. By way of general information, I did try the EV 638 FIRST! And when I received reports of mushy and otherwise bad audio, I tried adjusting things like the mike gain, drive, checked the ALC, and even my headphones, but to no avail. So, when all else failed, I read the manual. It just seemed to me that Kenwood had been making pretty good ham radios for a while and probably knew what they were doing when they spent the time and ink to go into detail (with warnings) about the mike sensitivity requirements. Frankly, I'd never bothered with mike sensitivity before, but they made the radio, so I decided to see if anyone else could offer advice. You have all been most helpful. If, someday, I can, I will help you.

Thanks for your time and recommendations. My apologies to anyone who has been insulted by my question.

73,

Karl - W4UTI

The dots show up when I stop tuning and that's on every band of my
TS-440S. In band or not cause the 440S is a general coverage receiver.
And of course no matter what antenna......

thanks

Not a case of being insulted Karl.
Most mike inserts die due to being bombarded with saliva and if you
smoke a coating of nicotine, tar and loads of other nasty chemicals. So
if that insert was not new and the HF response was poor and sounded
horrible it s time to chuck it in the bin. Or leave it for a few days
soaking in alcohol and see what colour the alcohol changes to, don't
waste good whiskey, user IPA or similar.
Then chuck it away.

Hi Scott,
Simple but not very obviouse, simply set the outer dial to the 25hz mark on the band set the VFO switch to the 25hz mark on the left, and while holding the outer dial turn the vfo knob the inner dial will move while you hold the outer dial still. the manual explains it much better than i do, HIHI. but it realy is a simple calibration.
hope this is at least a little helpfull

Okay, either the mike capsule is stuffed or the transformer has for some peculiar reason been removed. I've seen that before, and it led me a dance... Suffice to say that the end of a story that was longer than it should have been was "Mmm, wonder what happens if I plug it into a balanced input on the desk then?"

The outer scale slips round on the knob. You need to line it up for
pretty much every 25kHz "step", or at least I do on mine. Even at that,
my calibrator doesn't seem particularly "true" so I may need to break
out the frequency counter and Anthorn-disciplined reference...

Gordon,

Typically the 820 did not have an IF output.

My 820S does not have an IF output. The 2 RCA sockets on the rear of my 820, below the 8 pin octal socket, are "phone patch" connections. It appears your 820 is different, possibly a factory change or a previous owner mod, if you are not the original owner, was made to bring the "RIF" connection to the rear. It would be easy to determine which one by looking at the wiring. A factory modification/change more than likely would have the cabling embedded in the wiring harness, or neatly laced among the wiring harness. An owner modification may not have installed the wiring as neat as the factory would. I could be wrong but most mods I have seen that required wiring changes/additions were no where near as neat as factory wiring is. Anyway, have fun.

Hi Mike,
This is strange because even the service manual tells us to do
step 2-6 (Carrier Balance adjustment) measurement from the IF out
terminal on the rear connector. Page (47)
I know the 520 does NOT have the IF out, but every 820S I have worked on
does .
You sure you are talking about an 820S?
I shouldn't doubt you because you know as much or more about these
radios as anyone I know.

Hello Karl,

Not owning a 638 or familiar with it, I checked the datasheet for the EV 638 microphone and it is a dual-impedance mic. The sheet says exactly under Impedance, "150 ohms or HI-Z" (specify on order)". This leads me to believe that the microphone can be low or high impedance, but there is no provision for toggling the impedance in the mic itself. They must have factory-set the impedance. Therefore, you may have the 150 ohm model, when you need the HI-Z model. Maybe someone out there familiar with these can verify this.

On all of my 520s and 820s I have always used Astatic D-104s, Shure 444s or Kenwood HI-Z hand mics with good results.

Just my $0.02 on this issue.

As far as I know; there are no dumb questions, only dumb answers.

Best regards and 73, Lou Bellock N2JPR

Not a case of being insulted Karl.
Most mike inserts die due to being bombarded with saliva and if you
smoke a coating of nicotine, tar and loads of other nasty chemicals. So
if that insert was not new and the HF response was poor and sounded
horrible it s time to chuck it in the bin. Or leave it for a few days
soaking in alcohol and see what colour the alcohol changes to, don't
waste good whiskey, user IPA or similar.
Then chuck it away.

I have been looking in the archives but I can't seem to nail this one ,I want to tune my ts 520s but I am not getting an ALC reading on drive ,the driver tube has been replaced ,because I noticed the 10 meter band was hard to get an ALC max before all this started 18 months ago been idle since ,the finals are 10 years old but never been flogged ,nothing is burnt black or otherwise everything is pristine ,maybe I have dry caps or maybe someone can lead me to the ALC not working archives

Good morning Gordon and the group,

My mistake, I was wrong. The 820 does have an IF output RCA
socket on the upper right corner of the rear panel. I completely
forgot about that socket.

The 820's IF frequency, at that socket, is 8.83Mhz. I apologize for
my mistake.

Possibly on low-impedance versions they left the transformer out. In
which case, a little preamp will work wonders. A quick Gooooooooogle
suggests this:

http://www.zen22142.zen.co.uk/Circuits/Audio/dyn_mic/dyn_mic.htm

I haven't built this specific circuit, but it "looks right" (and it's
broadly similar to one I came up with to solve much the same problem
with instrument pickups). It's nicely unfussy and doesn't use any
hard-to-find bits.

Good Afternoon Group:

Mike, Gordon; looks like you beat me to it... yes, my TS-820S does indeed have the IF output on its back panel. Thanks to the groups responses, and a little detective work, it appears that the proper procedure to follow is:

From the SM-220 manual: "RECEIVE SIGNAL OBSERVATION" for receive signal observation, connect the transceiver IF #2 OUTPUT terminal to the SM-220, V. INPUT terminal. It goes on to talk about the settings, etc. See SM-220 manual page#10.

Thanks again to those kind enough to reply.

21417. TS-830S-Neutralization question

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-12 15:15:22 UTC
From: jmcphee@comcast.net
Topic: 21417 Message: 21417

Question-Rotation of the neutralization pot (TC-1) has no effect on the signal strength as displayed on the s-meter of a nearby receiver following the process outlined in the instruction manual. Does this indicate a problem?

Background-I am a new ham who purchased an 830S, through ebay, from an active ham. He indicated that it was not his primary rig, but that he used it successfully immediately prior to my buying it. When I initially tried to tune up the transmitter output (peak the drive, dip the plate), I got erratic meter reading. I checked the tubes, and found that one of the 6146Bs had a rattle, apparently caused by “something” loose inside. Although the transceiver was well packed, I suspected the tube had been damaged in transit. I replaced both 6146Bs with a matched pair of 6146Ws from RFPARTS, and also replaced the driver tube. I then followed the neutralization process as shown on page 28 of the instruction manual:

1. I tuned the xmitter into a dummy load on 28.500.

2. I set the SG switch off.

3. Stand-by switch to send.

4. Adjusted TC1 (at the bottom of the final section).

5. I observed the s-meter on a nearby receiver.

a. Using the rf gain of that receiver I had previously aligned the meter with a reference point.

6. The s-meter indicated a steady signal. It did not move while I rotated TC-1.

From: w5rkl
Topic: 21383 Message: 21418

Hi Tom and the group,

The connections to the Drain of Q4 in the 520, as shown in the SM-220 manual, taps the 520's 3.3Mhz IF signal at the primary of T6 on the IF UNIT board, just before it is fed to the Balance Detector on the Generator Unit. The same principle is accomplished in the 820 except the tap is accomplished on the 820's IF UNIT since the balance detector in the 820, not like in the 520 series, is located on the 820's IF UNIT.

The 520 series and 820 series have different IF frequencies. The 520 series IF frequency is 3.3Mhz and the 820 series IF frequency is 8.3Mhz. There are differences in how the "IF" frequency is created between the 520 and 820 series transceivers.

One main difference between the two different models, 820 verses 520, is the incoming signal is mixed "once" in the 820 to create the actual "IF" frequency but "twice" in the 520 series to create the actual "IF". See below on how this is accomplished.

520 series:

The amplified incoming signal in the 520 models is mixed on the RF UNIT with the local oscillator producing the 8Mhz "RIF" frequency. The "RIF" frequency, in all 520 models, is "NOT" the 520's actual IF frequency. The 8Mhz signal is fed to the IF UNIT where it is further mixed with the "VFO" signal to produce the actual "3.3Mhz" IF frequency.

820 series:

The amplified incoming signal is mixed with the "VCO" frequency on the RF UNIT producing the 8.3Mhz "RIF" frequency. Unlike the 8Mhz "RIF" frequency in the 520 models, the 8Mhz "RIF" frequency "is" the actual "IF" frequency in the 820 models.

The Kenwood BS-5 Pan Adapter is for the 520 series and the BS-8 Pan Adapter is for the 820 series. Therefore, a BS-5 will not work with an 820 and a BS-8 will not work with a 520.

21419. Re: TS-830S-Neutralization question

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-12 16:52:41 UTC
From: w5rkl
Topic: 21417 Message: 21419

Hello Jim,

Neutralization is not about reducing the operating frequency signal strength but rather reducing "spurious" signals that are outside of the operating frequency. Using a separate receiver as an indicator when neutralizing a final amplifier is not the route to take and you will always see the same S meter reading on the separate receiver when adjusting the neutralizing capacitor.

Your initial set up procedures are correct. However, once you have tuned the radio up into a dummy load to full output, set the "SG" switch to "OFF", you then connect an RF Probe that is connected to a VTVM or a scope probe connected to a scope to the rear SO-239 center pin and ground to the chassis. At that point you key the radio and adjust the neutralizing capacitor for a "minimum" reading on the VTVM OR scope display. You do NOT re-adjust the DRIVE, VFO, PLATE, and LOAD controls while neutralizing final amplifier, ONLY the neutralizing capacitor inside the final amplifier cage with a well insulated screw driver.

>
> Background-I am a new ham who purchased an 830S, through ebay, from an active ham. He indicated that it was not his primary rig, but that he used it successfully immediately prior to my buying it. When I initially tried to tune up the transmitter output (peak the drive, dip the plate), I got erratic meter reading. I checked the tubes, and found that one of the 6146Bs had a rattle, apparently caused by â□□somethingâ□□ loose inside. Although the transceiver was well packed, I suspected the tube had been damaged in transit. I replaced both 6146Bs with a matched pair of 6146Ws from RFPARTS, and also replaced the driver tube. I then followed the neutralization process as shown on page 28 of the instruction manual:

I've used a Heathkit HW-101 on PSK31. As long as the frequency is stable, it will work. Just run the output power bout 20 watts so you don't stress the finals with the high duty cycle.

Hi James,
The 520 is excellent for BPSK31. Use the phone patch sockets at the rear of the set. I get away with using an old IBM Thinkpad and no interface.

Tune up for max power as normal then use the mike gain and pc audio out to keep the plate current at around 125 - 150 mA. on transmit. Don't go higher than this as it's almost continuous duty for the old set and it won't like it. I tune up and then initially transmit into a dummy load until I'm sure everythings ok before going on the air. I've had reports of IMD -31dB which is about as good as it gets.

I've used a TS-520 on PSK31, 63, 125 and 250 with no problems at all. Just keep the power down, as others have said. You shouldn't need to run much power anyway. Since the PA is barely ticking over nothing gets hot or stressed.

I do find that the VFO drifts a lot in the first five to ten minutes, but that's okay because you just don't transmit until it settles down. You may find that even at that it jumps a few hundred Hz after the first over, but then behaves itself. Mine only does that when the room is quite cold.

Gordon

If I remember the sm220 with the bs-8 will only show the other station. It will NOT pan ... on the 820s see the manual (pg 14 i think)

21425. Re: TS-820S & SM-220

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-12 21:59:52 UTC
From: w5rkl
Topic: 21383 Message: 21425

Hello everyone,

The BS-5 and BS-8, when connected to the 520 or 820 series IF connections, do the same thing, display the signals within +/- 20Khz or +/- 100Khz band spread of the operating frequency. The operating frequency is the "center" of the 220's display. This is assuming the BS-5 or BS-8 have been aligned properly as stated in the SM-220 manual.

The 530 or 830 can be connected to the SM-220 adapter but only with the BS-8 since both the 530 and 830 have 8Mhz IF frequencies. Actually, any transceiver that has an IF frequency that is the same as the BS-5 or BS-8 can be connected to the SM-220 adapters. The radio doesn't have to be a Kenwood hybrid! The radio simply must have an IF frequency that is acceptable by either the BS-5 or BS-5 adapter to the SM-220. There is no requirement for any adapters for monitoring the transmitter signals, simply connect the transmitter and/or linear amplifier output to the rear SO-239 connections as shown in the SM-220 manual. Just because the SM-220 is manufactured by Kenwood does NOT mean you can only connect Kenwood transmitters or transceivers to it!

The IF frequencies of all 4 of the hybrids, and other ham gear as well, remains fairly constant but the incoming signal frequencies change.

If the VFO is tuned to 7.100 and a station is transmitting a carrier at 7.100, the carrier will be a vertical spike in the center of the display. Tuning the VFO either side of 7.100, the carrier spike will no longer be at the center of the display but will move left or right of center, depending on which direction the operator tunes the VFO.

The wave forms shown on page 10, figures 5-3 thru 5-6 and 5-7 of the SM-220 manual are the transmitter's wave forms produced by sampling the RF signal from the exciter and/or linear amplifier connected to the rear SO-239 IN/OUT connection. They have nothing to do with nor are they part of the BS-5 or BS-8 adapter signals.

The receive RTTY mark and space tones, as shown on page 12 figure 5-10, are "DC" voltages provided by an external Terminal Unit such as an AEA PK-232. The Terminal Unit "converts" the RTTY Mark and Space tones into DC voltages that, when connected as shown on page 12 figure 5-10, will display the cross hatch pattern. The Terminal Unit is not part of, nor is it included in, either the TS-520, TS-820, TS-530, TS-830, SM-220, BS-5 or BS-8.

The connection between the SM-220 and the 520, 820, 530, or 830, as shown on page 8 figure 5-1, is feeding the SB-220's tone generator, single tone or dual tones, into the microphone connection. The tones are selected from the SM-220's front panel. The SM-220 came equipped with a cable with a 3.5mm mono plug on one end and a 4 pin female microphone plug on the other, allowing the SM-220's tone generator to inject the tones into the microphone socket for testing and viewing of the transmitter's signal on the SM-220 display.

From: jmcphee@comcast.net
Topic: 21417 Message: 21426

Mike,

Thanks for your response. I tried to be very precise in describing the process I followed just so there would be no question about it, but let me try again.

I know what the purpose of the neutralization process is.

I followed the process (or the alternate process, perhaps) as defined in the instruction manual on page 28. I didn't make the process up.

The manual says, after describing how to proceed if you have a "sensitive RF milli-voltmeter", and I quote:

"A receiver tuned to 28.5 MHz works very well for neutralizing if an RF voltmeter is not available. Instead of tuning for a minimum voltage, tune for a minimum S-meter reading."

An RF voltmeter is not available (no scope, either) , so I followed the above process. I did not adjust anything other than the neutralization pot (with a plastic screwdriver) once the transmitter was tuned up and I began the neutralization process. So, the question remains:

Rotation of the neutralization pot (TC-1) has no effect on the signal strength as displayed on the s-meter of a nearby receiver following the process outlined in the instruction manual. Does this indicate a problem?

Subject: [TS-520_820_530_830] Re: TS-830S-Neutralization question

Hello Jim,

Neutralization is not about reducing the operating frequency
signal strength but rather reducing "spurious" signals that are
outside of the operating frequency. Using a separate receiver as an
indicator when neutralizing a final amplifier is not the route to
take and you will always see the same S meter reading on the
separate receiver when adjusting the neutralizing capacitor.

Your initial set up procedures are correct. However, once you
have tuned the radio up into a dummy load to full output, set the
"SG" switch to "OFF", you then connect an RF Probe that is connected
to a VTVM or a scope probe connected to a scope to the rear SO-239

center pin and ground to the chassis. At that point you key the
radio and adjust the neutralizing capacitor for a "minimum" reading
on the VTVM OR scope display. You do NOT re-adjust the DRIVE, VFO,
PLATE, and LOAD controls while neutralizing final amplifier,
ONLY the neutralizing capacitor inside the final amplifier cage
with a well insulated screw driver.

Hi Jim,

I understand the process you followed and why but imagine that your PA was spurious at say 22MHz. Your receiver tuned to 28.5MHz wouldn't (shouldn't) indicate anything. No matter how you adjust TC-1 your testing arrangement would not help you to reduce the 22MHz spurious.

I can't explain why that procedure is in the book (maybe the PA is prone to spurii at 28.5MHz) but certainly a 'scope or RF voltmeter would help confirm the PA was stable. Perhaps you can borrow some gear from a local club or amateur?

You indicate you've made some kind of reference measurement on your receiver. What do you mean and does it change when you hit the send switch. If so what do you read on receiver and transmit? Also, is the receiver connected to the 830 or really just sitting nearby with no aerial connection?

As I write I'm thinking that even if you can't find a scope or RF voltmeter you could use the receiver to look for spurrii by tuning up and down the bands whilst toggling the send switch on the 830. Lots more work for you but it should help put your mind at rest.

Regards

Lou

Topic: 21383 Message: 21429

G'Day
I posted a question re this subject a week or to ago . I have a ts 530sp and a sm220. There has been a lot of talk about the if out of the 530 series radio. This 530sp has no if outputs at all on the back it has a couple of accesories holes that could take the fittings needed , and they still have the silver tape over them from new. I believe i need 2 outputs from the if. One for the v input and the other for the pan adaptor. So my question is has anyone ever modified their 530sp and wired in the 2 if outputs needed for the sm220.
Also does anyone know if they are the same as an 830 because a mate has one down the road that i may be able to con him into letting me pull the cover off to find where the if comes from on the board.
Any help would be greatly appreciated

According to what I've read and seen in the SM-220 operating manual, the IF output jack on the back of the TS-820 is meant to be connected to the vertical input (front panel) of the SM-220. This connection allows you to see the received signal on the scope. This signal is on the output side of the last IF chain. That connection on the back of the TS-820 is not for the pan adapter display of the SM-220. Note: This connection also requires some component modification when the SM-220 is used with the TS-820 (see Page 9 of the SM-220 operating manual). You normally extracted a signal for pan adapter viewing on the input side of the first IF. Page 16 of the SM-220 operating manual clearly defines how you have to make the internal connection for the pan adapter cable on either the TS-520 or TS-820.

Topic: 21383 Message: 21432

Hello Pete,

The SM-220 can be used as a simple 2Hz to 10Mhz simple oscilloscope. The vertical and horizontal BNC connectors are "inputs" for the OSC/RTTY FUNCTION switch position. The only benefit to connecting the transceiver's IF output to the vertical BNC input connector is to display the IF signal level. Connecting the transceiver's IF input this way will NOT provide the display features the BS-5 or BS-8 provides.

The modifications shown on page 16, figure 8-5 are for the "520" NOT the 820.

The modification shown on page 16, figure 8-6 is for TS-820's that do NOT have an IF output on the rear panel. If the 820 has an IF output on the rear panel, the modification shown on page 16, figure 8-6 is NOT required!

The addition of the two resistors, 150 ohm and 10K ohm, shown on page 9 figure 5-2, is required to reduce the level of the IF signal from the 820 that connects to the BS-8 pan adapter plug in module on the rear of the SM-220, nothing more.

In order to use the BS-5 or BS-8 when installed in the SM-220, the transceiver's IF output MUST be connected to the rear RCA socket on the SM-220. The font panel BNC vertical and horizontal connections will not connect to the BS-5 or BS-8.

Hello Barry,

ALC is a transmitter ONLY control voltage and is only produced
when grid current flows in the final tubes.

When the transmitter's driving signal causes the final tube
grids to become positive, a current flows between the final tube
cathodes and grids. When this occurs, the ALC circuit senses this
and creates ALC voltage. The ALC voltage varies at the same rate
as the RF driving signal. The ALC voltage is then fed back to
an earlier stage, normally the transmitter's IF amplifier, causing
a reduction in the IF amplifier's gain which ultimately results
in a reduction in the final amplifier's output. ALC voltage works
just like a receiver's AGC voltage does, controls the gain of the
transmitter.

If the level of ALC voltage fed back to the IF amplifier is equal
to or less than the operating bias of the IF amplifier, no gain
reduction in the IF amplifier occurs. Gain reduction in the IF
amplifier ONLY occurs if the ALC voltage exceeds the operating bias
of the IF amplifier and not until then.

When the final tube grids become positive, gird current flows, and
ALC voltage is produced, just as I state above. However, when
this occurs, the final amplifier is no longer operating in a linear
state and the output signal becomes distorted. ALC is designed to
lower the gain of an earlier stage in order to allow the final
amplifier to return to its linear state.

The bottom line is, the lower the ALC indication the cleaner your
signal will be.

ALC is NOT used in CW because the transmitter's output level is
"manually" controlled by the CAR control. The CAR control is used
in both TUNE and CW modes but has absolutely no control what so
ever in sideband (USB or LSB).

ALC works like AGC does in a receiver, except it is produced
ONLY in the transmitter, never in the receiver.

Mike:
I think you need to go back and read the SM-220 operating manual. It clearly states in Section 8.6, page 16 of the SM-220 operating manual, that the TS-520 and TS-820 have no Pan Display output terminals. It also provides the construction details for connecting the IF sample cable and added parts to the TS-520 and TS-820. This IF cable is what connects to the input of the BS-5 or BS-8 for pan adapter operation. The connections for the transceiver pan adapter output are exited at the 8 pin Remote plug.

It also clearly states in Section 5.2, Receive Signal Observation, page 9 of the SM-220 operating manual, "for receive signal observation, connect the TS-820S IF OUTPUT terminal to the SM-220 V (vertical) INPUT terminal". The addition of two resistors (voltage divider) is also required to be installed. This connection is no different then connecting the vertical input of a typical scope to the IF OUTPUT terminal(jack) on the back of the TS-820. Also in Section 5.2, there is a Section labeled TS-520/S IF Output Installation (May be installed at the time of BS-5/BS-8 modification). This modification will allow the TS-520/S to connect to the vertical input (V input) of the SM-220 for receive signal observation. NOTE: Receive signal observation has nothing to do with the BS-5 or BS-8 pan adapter. The receive signal observation, with the front panel SM-220 switch set to OSC/RTTY, allows you to view modulated SSB and AM waveforms and also to view CW signals and yes, if vertical and horizontal input connections are made, to view RTTY signals.

The SM-220 allows three types of viewing on the CRT. (1) You can view your transmitted waveform, (2) with the BS-5/BS-8, you can sweep and view up to +/- 100 KHz on either side of center received frequency, and (3) you can view in the OSC/RTTY position, the modulated waveforms of the received signals. The transceiver or receiver require two different connections to the rig. Pan adapter operation is generally done with signals before they enter the IF section of the receiver and "receive signal observation" (looking at the received waveforms) is generally done at the output of the IF section which generally is the input of detector stage. When the TS-830S was intrduced, it has two phono type jacks on the back (IF1 and IF2) to interface with the SM-220 to allow you to do both (2) and (3) without any additional internal wiring.

Hi Kevin, I use both a Shure 444 mic (you can find these every where) and an old Motorola hand mic (a taxi mic) with my TS520s and consistently receive good audio reports. Good luck with the 520s, as I really enjoy mine.
Alex

HI All,

Just aquired a TS-520S in good condition for it's age.

Has a good RX and TX is excellent with 130 watts into a matched antenna and dummy load.

However a couple of minor issues I would like to fix

1. the VOX switch is broken, is there replacement swtiches to fix?

2. The mic was lost from the owner and replaced with a GE CB mic. The impedenace are the same, just would be nice to have a Kenwood mic.

Not much else to know about this radio, need to get it on the desk and fully look it over and try it out.

Regards

Kevin, ZL1KFM.

Mike,

Thanks for your response. I tried to be very precise in describing the process I followed just so there would be no question about it, but let me try again.

I know what the purpose of the neutralization process is.

I followed the process (or the alternate process, perhaps) as defined in the instruction manual on page 28. I didn't make the process up.

The manual says, after describing how to proceed if you have a "sensitive RF milli-voltmeter" , and I quote:

"A receiver tuned to 28.5 MHz works very well for neutralizing if an RF voltmeter is not available. Instead of tuning for a minimum voltage, tune for a minimum S-meter reading."

An RF voltmeter is not available (no scope, either) , so I followed the above process. I did not adjust anything other than the neutralization pot (with a plastic screwdriver) once the transmitter was tuned up and I began the neutralization process. So, the question remains:

Rotation of the neutralization pot (TC-1) has no effect on the signal strength as displayed on the s-meter of a nearby receiver following the process outlined in the instruction manual. Does this indicate a problem?

Subject: [TS-520_820_ 530_830] Re: TS-830S-Neutralizat ion question

Hello Jim,

Neutralization is not about reducing the operating frequency
signal strength but rather reducing "spurious" signals that are
outside of the operating frequency. Using a separate receiver as an
indicator when neutralizing a final amplifier is not the route to
take and you will always see the same S meter reading on the
separate receiver when adjusting the neutralizing capacitor.

Your initial set up procedures are correct. However, once you
have tuned the radio up into a dummy load to full output, set the
"SG" switch to "OFF", you then connect an RF Probe that is connected
to a VTVM or a scope probe connected to a scope to the rear SO-239
center pin and ground to the chassis. At that point you key the
radio and adjust the neutralizing capacitor for a "minimum" reading
on the VTVM OR scope display. You do NOT re-adjust the DRIVE, VFO,
PLATE, and LOAD controls while neutralizing final amplifier,
ONLY the neutralizing capacitor inside the final amplifier cage
with a well insulated screw driver.

> Background-I am a new ham who purchased an 830S, through ebay, from an active ham. He indicated that it was not his primary rig, but that he used it successfully immediately prior to my buying it. When I initially tried to tune up the transmitter output (peak the drive, dip the plate), I got erratic meter reading. I checked the tubes, and found that one of the 6146Bs had a rattle, apparently caused by â€œsomethingâ€? loose inside. Although the transceiver was well packed, I suspected the tube had been damaged in transit. I replaced both 6146Bs with a matched pair of 6146Ws from RFPARTS, and also replaced the driver tube. I then followed the neutralization process as shown on page 28 of the instruction manual:

Lou,

As I indicated, I am a novice at this, although I have some background in radios and communications thanks to the USN some years back.

The only deviation the "alternate" process takes from Kenwood's documented "primary" process is to use the s-meter on the nearby receiver as opposed to using a RF voltmeter. Why the Kenwood engineers specified 28.500 as the frequency of choice for the neutralization process I sure don't know, BUT I've got to think that if they could engineer a transceiver as good as these hybrids that they knew what they were doing. There's only one neutralization pot, and only 360 degrees on it, and no access port through the bottom of the case (the case needs to be removed to access it) so you have to make your adjustments before putting the case back on. How one would make different adjustments(if that's what you're suggesting) between 10 and 160 meter bands I don't know. Seems like you "could" chase it all over the place on the different bands. Tuning the pot to the lowest voltage or signal level on another receiver is Kenwood's documented process and the one I will follow until I know or am told of a better one.

Here is the process that Ken at K4EAA.COM recommends on his website:

How can I Neutralize my Finals?
Neutralization is the process of compensating for the inter-electrode capacitance of the final tubes. It helps prevent the tubes from oscillating, and allows them to perform as a stable amplifier. Here is a simple sequence for neutralizing your finals:
(1) Tune up normally into a dummy load on 10M, perhaps 28.1 MHz
(2) Turn your SG (Screen Grid voltage) switch OFF. This effectively turns off your finals, and will prevent them from putting any power into your measurement setup.
(3) If your dummy load has external connections to monitor the RF it is seeing, use those - Otherwise, remove the dummy load and replace it with a 50 ohm resistor (47 or 51 Ohms, 1/2W will work fine) that is mounted onto a PL-259 Plug. During neutralization there is no significant power in the load, so use what's handy.
(4) Using an RF millivoltmeter or oscilloscope with at least 20MHz bandwidth, connect it across the small 50 Ohm test load. A 20MHz scope will display 28 MHz adequately, although it won't accurately measure the RF voltage present. That's OK, because when we neutralize, we're simply tuning for minimum output.
(5) Key the rig and observe the output voltage on your RF VTVM or Scope. This is the drive power "leaking through" to the load with the finals inoperative. Our goal here is to minimize this leakage, and in doing so, we will ne "neutralizing" the inter-electrode capacitance.
(6) Using an INSULATED tool, either plastic or a carved wooden dowel, tune

the neutralization capacitor for minimum output. You should be able to get down to 10 millivolts or so. There is LOTS of voltage present, so don't even THINK about using a metallic tool!! You will spark and arc and create all manner of scarey fireworks if you do - Not to mention perhaps joining the ranks of the SK's . . .
Don't forget to return your SG switch to ON for normal operation.
Same basic process, just a slightly lower 10 meter frequency with the option of using a scope to tune for a minimum output.

In answer to your question about the nearby receiver, it was truly that. Sitting a couple of feet away with no physical connection. Once I had hit the send switch on the 830S, the other receiver picked up the signal from the 830S. I adjusted the RF gain on that other receiver to align the needle with a reference point, say the s7 mark. My thinking was I would have a reference point so I could watch for any deviation above or below that mark with a goal of setting the neutralization pot so that the needle on the other receiver was at its lowest point. Trouble is there was no lowest point; in fact there was no deviation at all.

Subject: Re: [TS-520_820_530_830] Re: TS-830S-Neutralization question

Hi Jim,

I understand the process you followed and why but imagine that your PA was spurious at say 22MHz. Your receiver tuned to 28.5MHz wouldn't (shouldn't) indicate anything. No matter how you adjust TC-1 your testing arrangement would not help you to reduce the 22MHz spurious.

I can't explain why that procedure is in the book (maybe the PA is prone to spurii at 28.5MHz) but certainly a 'scope or RF voltmeter would help confirm the PA was stable. Perhaps you can borrow some gear from a local club or amateur?

You indicate you've made some kind of reference measurement on your receiver. What do you mean and does it change when you hit the send switch. If so what do you read on receiver and transmit? Also, is the receiver connected to the 830 or really just sitting nearby with no aerial connection?

As I write I'm thinking that even if you can't find a scope or RF voltmeter you could use the receiver to look for spurrii by tuning up and down the bands whilst toggling the send switch on the 830. Lots more work for you but it should help put your mind at rest.

Subject: RE: [TS-520_820_530_830] Re: TS-830S-Neutralization question

Lou,

As I indicated, I am a novice at this, although I have some background in radios and communications thanks to the USN some years back.

The only deviation the "alternate" process takes from Kenwood's documented "primary" process is to use the s-meter on the nearby receiver as opposed to using a RF voltmeter. Why the Kenwood engineers specified 28.500 as the frequency of choice for the neutralization process I sure don't know, BUT I've got to think that if they could engineer a transceiver as good as these hybrids that they knew what they were doing. There's only one neutralization pot, and only 360 degrees on it, and no access port through the bottom of the case (the case needs to be removed to access it) so you have to make your adjustments before putting the case back on. How one would make different adjustments(if that's what you're suggesting) between 10 and 160 meter bands I don't know. Seems like you "could" chase it all over the place on the different bands. Tuning the pot to the lowest voltage or signal level on another receiver is Kenwood's documented process and the one I will follow until I know or am told of a better one.

Here is the process that Ken at K4EAA.COM recommends on his website:

How can I Neutralize my Finals?
Neutralization is the process of compensating for the inter-electrode capacitance of the final tubes. It helps prevent the tubes from oscillating, and allows them to perform as a stable amplifier. Here is a simple sequence for neutralizing your finals:
(1) Tune up normally into a dummy load on 10M, perhaps 28.1 MHz
(2) Turn your SG (Screen Grid voltage) switch OFF. This effectively turns off your finals, and will prevent them from putting any power into your measurement setup.

(3) If your dummy load has external connections to monitor the RF it is seeing, use those - Otherwise, remove the dummy load and replace it with a 50 ohm resistor (47 or 51 Ohms, 1/2W will work fine) that is mounted onto a PL-259 Plug. During neutralization there is no significant power in the load, so use what's handy.
(4) Using an RF millivoltmeter or oscilloscope with at least 20MHz bandwidth, connect it across the small 50 Ohm test load. A 20MHz scope will display 28 MHz adequately, although it won't accurately measure the RF voltage present. That's OK, because when we neutralize, we're simply tuning for minimum output.
(5) Key the rig and observe the output voltage on your RF VTVM or Scope. This is the drive power "leaking through" to the load with the finals inoperative. Our goal here is to minimize this leakage, and in doing so, we will ne "neutralizing" the inter-electrode capacitance.
(6) Using an INSULATED tool, either plastic or a carved wooden dowel, tune the neutralization capacitor for minimum output. You should be able to get down to 10 millivolts or so. There is LOTS of voltage present, so don't even THINK about using a metallic tool!! You will spark and arc and create all manner of scarey fireworks if you do - Not to mention perhaps joining the ranks of the SK's . . .
Don't forget to return your SG switch to ON for normal operation.

21439. Re: TS-820S & SM-220

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-13 16:46:19 UTC
From: w5rkl
Topic: 21383 Message: 21439

Hello Pete,

I may not have been as clear as I should have in my recent response regarding this topic.

I have read the SM-220 manual and I do not disagree, never did, that the SM-220 manual states the IF signal can be displayed by connecting it to the vertical input. What I did say was that by connecting the IF signal to the vertical input, the displayed IF signal will not be the same as the display produced by the BS-5 or BS-8 pan adapters but rather the IF signal level will be displayed. I agree it is possible to display SSB and CW wave forms by connecting the IF signal to the vertical input but the display is limited to the single signal present at 8.3Mhz IF frequency.

As you know, the BS-5 or BS-8 pan adapters, when installed in the SM-220 and connected to the IF output, display a +/- 20Khz or +/- 100Khz snap shot of real time receive bandwidth of the receiver's selected band, including all the signals within the selected bandwidth. However, the display produced by the BS-5 or BS-8 is not possible when connecting the IF output signal to the SM-220's vertical input and setting the Function switch to OSC/RTTY. The SM-220 BS-5 and BS-8 pan adapters produce a display that is similar to other pan adapter scopes such as the Heathkit SB-620.

I also agree that the RF output wave forms of the exciter and linear amplifier can be displayed as stated in the SM-220 manual. This is basically the same as other monitor scopes such as the Heathkit SB-610 for example.

You said early models of the 820 had 2 IF outputs on the rear, IF1 and IF2. That may be so, I can't say one way or the other. However, what I did say was, if the 820 already has an IF output then the modification on page 16 figure 8-6 is not required. The 520 mod is required since the 520 does not have an IF output.

I agree, the IF tap should be made at the input to the detector. The 820 factory IF OUT along with the 520 modification shown on page 16 figure 8-5 does just that. However, the 820 modification on page 16 figure 8-6 does not connect to the detector's input but rather to the IF UNIT's PC board foil "RIF" connection which is the same as the IF UNIT's IF1 pin 1 plug. Having said that, both connection produce the same results, an IF signal output on the rear panl, whether it be through the 8 pin octal socket or by drilling a hole and mounting an RCA socket on the rear panel. There is a difference between the SM-220 820 IF UNIT modification and the

factory IF output. The factory IF OUT is "after" the crystal filters and the SM-220 modification is "before" the crystal filters. Again, the result is the same, the IF signal is made available at the rear panel.

I agree, the resistive voltage divider modification is required, never said it wasn't. However, I will add that if the IF output will never be fed to the pan adapter or any circuit that requires a lower signal level than the IF output provides, then the voltage divider network modification to the IF output on the 820 is not required. However, if, in the future, the BS-8 pan adapter is installed in the SM-220, the resistive voltage divider network will need to be installed. Installing it now will eliminate that step if the BS-8 is installed in the future. Whether the IF output is connected to a BS-8 or not or even if the IF output is connected to a vertical input whether it be to the SM-220 or an oscilloscope, having the voltage divider network installed will not affect the operation of the 820.

Mike,

Yes, the process calls for both the 830s transmitter, and the adjacent receiver, to be set on the same frequency. This is not an attempt to measure spurious emissions, it is the Kenwood documented process for eliminating or at least reducing spurious emissions when installing a new set of drivers.

Mike,

Thanks for your response. I tried to be very precise in describing the process I followed just so there would be no question about it, but let me try again.

I know what the purpose of the neutralization process is.

I followed the process (or the alternate process, perhaps) as defined in the instruction manual on page 28. I didn't make the process up.

The manual says, after describing how to proceed if you have a "sensitive RF milli-voltmeter" , and I quote:

"A receiver tuned to 28.5 MHz works very well for neutralizing if an RF voltmeter is not available. Instead of tuning for a minimum voltage, tune for a minimum S-meter reading."

An RF voltmeter is not available (no scope, either) , so I followed the above process. I did not adjust anything other than the neutralization pot (with a plastic screwdriver) once the transmitter was tuned up and I began the neutralization process. So, the question remains:

Rotation of the neutralization pot (TC-1) has no effect on the signal strength as displayed on the s-meter of a nearby receiver following the process outlined in the instruction manual. Does this indicate a problem?

Subject: [TS-520_820_ 530_830] Re: TS-830S-Neutralizat ion question

Hello Jim,

Neutralization is not about reducing the operating frequency
signal strength but rather reducing "spurious" signals that are
outside of the operating frequency. Using a separate receiver as an
indicator when neutralizing a final amplifier is not the route to
take and you will always see the same S meter reading on the
separate receiver when adjusting the neutralizing capacitor.

Your initial set up procedures are correct. However, once you
have tuned the radio up into a dummy load to full output, set the
"SG" switch to "OFF", you then connect an RF Probe that is connected
to a VTVM or a scope probe connected to a scope to the rear SO-239
center pin and ground to the chassis. At that point you key the
radio and adjust the neutralizing capacitor for a "minimum" reading
on the VTVM OR scope display. You do NOT re-adjust the DRIVE, VFO,
PLATE, and LOAD controls while neutralizing final amplifier,
ONLY the neutralizing capacitor inside the final amplifier cage
with a well insulated screw driver.

indicated that it was not his primary rig, but that he used it successfully immediately prior to my buying it. When I initially tried to tune up the transmitter output (peak the drive, dip the plate), I got erratic meter reading. I checked the tubes, and found that one of the 6146Bs had a rattle, apparently caused by â€œsomethingâ€? loose inside. Although the transceiver was well packed, I suspected the tube had been damaged in transit. I replaced both 6146Bs with a matched pair of 6146Ws from RFPARTS, and also replaced the driver tube. I then followed the neutralization process as shown on page 28 of the instruction manual:

Hello Jim,

I'm not doubting you and yes, I agree, it does say a separate
receiver tuned to 28.5Mhz can be used in place of an RF volt meter.
I've never used that method when neutralizing the final amplifier.
I've always used an RF probe connected to a VTVM or an oscilloscope,
connected to the center pin of the SO-239 and adjusted the
neutralizing cap for a minimum indication on the meter or scope.

He indicated that it was not his primary rig, but that he used it successfully immediately prior to my buying it. When I initially tried to tune up the transmitter output (peak the drive, dip the plate), I got erratic meter reading. I checked the tubes, and found that one of the 6146Bs had a rattle, apparently caused by Ã¢â□¬Å"somethingÃ¢â□¬ï¿½ loose inside. Although the transceiver was well packed, I suspected the tube had been damaged in transit. I replaced both 6146Bs with a matched pair of 6146Ws from RFPARTS, and also replaced the driver tube. I then followed the neutralization process as shown on page 28 of the instruction manual:

It sounds as if the receiver is receiving the signal radiated from
leakage from the EUT.
You could try connecting a short antenna to the SO-239 which will
increase the received signal level, but will at least be effected by
the level coming out of the EUT aerial connector.

You could also, if you have one, use a analog multimeter on the AC
range, the cheap ones only use a single small signal diode as a
rectifier. And if its one of the really cheap ones $5 from your local
hardware store, its small and the length of the internal wiring will be
short.I'm referring to the cheap analog handheld meters that are about
2"x 3" in size.

From: Lou Blasco
Topic: 21417 Message: 21443

Hi Jim,

Firstly to your delayed posts. I'm not sure if you're a new member or not but it could be that your membership has the "moderation" button selected. I had this with a couple of other Yahoo sites that I've joined. My posts would be delayed for hours or even days. After a few emails back and forth to the moderators it was finally sorted out. Seems there's something funny with the way Yahoo profiles are configured.

On the topic of 28.5MHz, I think you're right, Kenwood know what they're doing. My suggestion to look for spurii with your receiver was plain nonsense. So I went out into the shack this morning and replicated your test configuration. I used a Kenwood 520S, a Kenwood R2000 receiver (no aerial and the SO-239 unterminated) and my AT200 dummy load. I also prepared an electronic RF millivolt meter with 50 ohm terminated load. The receiver was on the same desk as the 520S two feet away. I tuned up into the load and tuned the receiver so I could detect the signal (about S9 +20dB) with the SEND switch on.

Then I turned off the filaments and the SG switch and hit SEND. The signal was barely audible and the meter moved maybe half an S point (around S1). Next step was to remove the covers and go through the neutralization procedure. Well there it was. With the covers off I had an S7 signal on the receiver. I agree with Richard that the signal you're receiving is radiated from inside the 830 rather than the aerial connector of your 830.

I found the same thing you did. No matter where TC-1 was set the receiver showed the same signal strength. I then connected the RF millivolt meter in place of the AT200 and adjusted TC-1 for minimum output from the 520S. I measured less than 1mV into a 50 ohm termination. The S meter on the receiver did not move. The small adjustment made with TC-1 has no impact on the radiated signal from the unshielded 830.

My conclusion is that there is no way you can run the neutralization procedure with your test configuration.

So your original question was "Do I have a problem with my 830"? Probably not but you need to find a way to confirm that your PA is correctly neutralized. Is there any chance you could borrow a 'scope or RF voltmeter?

Lou,

Yes, I am a new member, so maybe my posts are being "reviewed?" prior to being released to the forum. I'll be patient and hope that I'm given "trusted poster" status soon.

Wow. What can I say? You went to a lot of trouble to validate or invalidate Kenwood's (alternate) process. It sounds like the process of monitoring a signal on an adjacent receiver to set the lowest voltage of the neutralization circuit may be suspect.

I had a email off-line from another forum member who had the same experience you and I had. He elected to proceed to use his new tubes and has been transmitting successfully for several months now, perhaps(and I acknowledge this is not a scientific conclusion) indicating that the new tubes did not require any neutralization. The questions begs to be asked, is there a way to determine the success or failure of the neutralization process? How does one determine, with a high degree of certainty, that a transmitter is, or isn't, generating spurious emissions following the fitment of new final amp tubes. We know Kenwood thought enough of their process to document it in their manual, so maybe what we are seeing are situations where tubes are of such high quality or closely matched tolerances that neutralization is not an issue.

The process calls for the voltage to be set at the lowest measurable setting. What did you find to be the range between the highest measurable voltage and the lowest while having your meter connected? Was there a significant difference? Did you find that the base setting, before you adjusted TC-1, was the lowest, or did you end up at a different setting when you were done than when you began?

Once again, I'm glad you duplicated the process I followed and posted your results. Thanks for going to the trouble.

Mike:
Sorry I didn't respond sooner, but VHF contest is this weekend and, 6 meters has been hopping all day.

I'm going to respond to each paragraph directly under each paragraph. And, to all that may be reading this, and Mike correct me if I misinterpreted your position. Mike contends that the IF Output jack on the back of the TS-820/820S (I'm just going to use this model) can be connected to the input of the BS-8 to provide the pan adapter function in the SM-220. I say that this not true, and Kenwood, through their documentation, also says that this not true. Now, let's move down to the various paragraphs below. My responses will be preceded with "****#".

On Sat, 13 Jun 2009 16:46:19 -0000 "w5rkl" <w5rkl@...> writes:
>
Hello Pete,
>
You said: I may not have been as clear as I should have in my recent response regarding this topic.
I have read the SM-220 manual and I do not disagree, never did, that the SM-220 manual states the IF signal can be displayed by connecting it to the vertical input. What I did say was that by connecting the IF signal to the vertical input, the displayed IF signal will not be the same as the display produced by the BS-5 or BS-8 pan adapters but rather the IF signal level will be displayed. I agree it is possible to display SSB and CW wave forms by connecting the IF signal to the vertical input but the display is limited to the single signal present at 8.3Mhz IF frequency.

****1. I agree and note that this IF signal comes from the IF jack (labeled IF Output) in the back of the TS-820.

You said: As you know, the BS-5 or BS-8 pan adapters, when installed in the SM-220 and connected to the IF output, display a +/- 20Khz or +/- 100Khz snap shot of real time receive bandwidth of the receiver's selected band, including all the signals within the selected bandwidth. However, the display produced by the BS-5 or BS-8 is not possible when connecting the IF output signal to the SM-220's vertical input and setting the Function switch to OSC/RTTY. The SM-220 BS-5 and BS-8 pan adapters produce a display that is similar to other pan adapter scopes such as the Heathkit SB-620.

****2. The issue here is "IF output". Actually, per Kenwood's schematic drawings on the TS-820 and the SM-220 modification information I posted earlier, the BS-8 (for the TS-820) is connected to the TS-820's input side of the IF section. See further information in #5 below

You said: I also agree that the RF output wave forms of the exciter and linear amplifier can be displayed as stated in the SM-220 manual. This is basically the same as other monitor scopes such as the Heathkit SB-610 for example.

****3. Full agreement.

You said: You said early models of the 820 had 2 IF outputs on the rear, IF1 and IF2. That may be so, I can't say one way or the other. However, what I did say was, if the 820 already has an IF output then the modification on page 16 figure 8-6 is not required. The 520 mod is required since the 520 does not have an IF output.

****4. I actually said TS-830S, not the 820, has two IF connections (IF1 and IF2). One is on the input side of the IF section for connection to the BS-8 and the other is on the output side of the IF section for connection to the vertical input on the front panel of the SM-220.

You said: I agree, the IF tap should be made at the input to the detector. The 820 factory IF OUT along with the 520 modification shown on page 16 figure 8-5 does just that. However, the 820 modification on page 16 figure 8-6 does not connect to the detector's input but rather to the IF UNIT's PC board foil "RIF" connection which is the same as the IF UNIT's IF1 pin 1 plug. Having said that, both connection produce the same results, an IF signal output on the rear panel, whether it be through the 8 pin octal socket or by drilling a hole and mounting an RCA socket on the rear panel. There is a difference between the SM-220 820 IF UNIT modification and the factory IF output. The factory IF OUT is "after" the crystal filters and the SM-220 modification is "before" the crystal filters. Again, the result is the same, the IF signal is made available at the rear panel.

****5. Let me repeat this paragraph from the SM-220 operating manual: "The TS-520 and TS-820 series transceivers have no Pan Display output terminals. The coaxial cable supplied with the BS-5/BS-8 must be installed as follows...." This is on Page 16, Section 8.6 of the SM-220 manual. I also checked all the issues of the TS-820, 820S operating manuals, and they all showed the IF Output jack installed in the transceivers. The TS-820 was never without this jack but this jack was never for a connection to the BS-8.

The reason the modification shows the connection (for the pan display) to IF UNIT's PC board foil "RIF" connection is that you always want the pan adapter display to view the signals before they enter the IF chain. Since the pan adapters first came on the market in the 40's, the pan adapter signal pick-off point has always been the before the IF chain (early tube radios made the connection with a small cap connected to the mixer tube plate terminal. The mixer feeds the IF chain). This configuration is no different (conceptually) then what is in the TS-820 or 520 series. The input and output sides of the IF chain are completely different in terms of what type of signal you are looking for to drive pan adapter display(BS-8/BS-5) or the vertical input of the SM-220 (just to view single signal waveforms). The IF strip tailers the signal with

crystal/ceramic SSB or CW filters and/or modifies the overall response with transformers and/or R/C networks as it passes through the various sections. You really can't display a +/- 20Khz or +/- 100Khz snap shot of real time receive bandwidth on the SM-220 pan adapter display when you're trying to view it after it goes through a 2.4 KHz or 2.8 KHz SSB filter. The pan adapter connection at this output point (IF Output on the TS-820/820S) becomes somewhat meaningless, which is why you need to make the modification as described in the SM-220 operating manual.

You said: I agree, the resistive voltage divider modification is required, never said it wasn't. However, I will add that if the IF output will never be fed to the pan adapter or any circuit that requires a lower signal level than the IF output provides, then the voltage divider network modification to the IF output on the 820 is not required. However, if, in the future, the BS-8 pan adapter is installed in the SM-220, the resistive voltage divider network will need to be installed. Installing it now will eliminate that step if the BS-8 is installed in the future. Whether the IF output is connected to a BS-8 or not or even if the IF output is connected to a vertical input whether it be to the SM-220 or an oscilloscope, having the voltage divider network installed will not affect the operation of the 820.

****6. The reason for the voltage divider on the IF Output jack is that, without it, there is too high of a voltage signal level being connected to the vertical input of the SM-220. So, the two resistors provide a bit of attenuation. Remember, the IF Output jack is connected to the last stage of the IF amplifiers so the signal level is somewhat high.

You may or may not have seen this, but in the SM-220 operating manual, Figure 5.1, page 8, also shows the cabling from the IF Output jack on the rear of the TS-820S connected to the front panel vertical input connection. Obviously, if this jack was suitable for connection to the pan adapter, why didn't Kenwood mentioned this in the SM-220 operating manual. They specifically said in the SM-220 operating manual: "The TS-520 and TS-820 series transceivers have no Pan Display output terminals". Note, one could modify the TS-820 IF Output jack by removing the existing connections and adding the required modification for a BS-8 connection to this same jack rather then to the remote jack.

**** Sorry for the long dissertation but I felt it was important that we all get an understanding as to what connects to what and what are the ramifications if it's connected to the wrong what. Bottom line: pan adapters need to be connected to a point where the signal enters the first section of the receiver/transceiver IF chain and not at the output end of the IF chain. Anyway, that's my story and I'm sticking to it. Been SM-220 user since the late 70's.

21446. RE: [TS-520_820_530_830] Re: TS-830S-Neutralization question

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-14 05:18:27 UTC
From: Lou Blasco
Topic: 21417 Message: 21446

Hi Jim,

The maximum voltage I had from my radio (original set of 2001's) was less than three mV into the 50 ohm load. I did find that the 'best' spot for TC-1 was a broad range of around 50% of it's rotation. Mine was already adjusted to minimum so there was no change before/after. I tried to see if the plates were meshed or not but I couldn't get the right viewing angle due to the cramped conditions. I recall in a previous life I had to work on 15kW pulsed amplifiers used in MRI service. Neutralization was the first step after the tube was changed. From memory, the best adjustment for those tubes was also pretty broad.

I doubt that tubes have changed that much that neutralization is no longer required. They're still built to the same specification as 20 - 30 or more years ago. It's possible that tube manufacturing tolerances are so close however that one set of tubes has the same characteristics as the next. In that case you 'might' get by without going through the neutralization step. I don't have a lot of practical experience with tube neutralization but I expect the danger is more likely to occur at full power on the higher bands where the small values of inter-electrode capacitance in the tubes come into play at the higher frequencies. Me, I wouldn't do it. Easy for me because I have the test gear to do the job.

How do you know if your neutralization is correct? You need to measure the leakage with no power applied to the PA. You could tune your receiver around the 10m band while you have the send switch on and see if you can hear other signals from the 830. Put all the covers on and listen around. I expect that the received signal on 28.5MHz should be quite low (S1 or less) and there should be nothing else.

If you really can't get a hold of some test equipment, do you at least have a multimeter? You could whip up a little rf probe adapter that although not accurate will probably give you at least some indication of RF at the aerial socket.

http://www.google.com.au/search?hl=en&safe=off&num=50&newwindow=1&q=rf+probe+circuit&btnG=Search&meta=

I tried connecting the receiver directly to the 520 via an attenuator & coax but the radiation from the 520 was getting into the radio from all over so it was impossible to use my receiver as some kind of selective volt meter. Probably says more about my receiver than it does about the testing technique.

Maybe someone else has other ideas about how you can complete this
task. It must be really frustrating considering this is normally a
two minute job.

My experience of audio valves is that the much-derided Eastern European EL34s are very tight these days - any two at random out of the box will be a closer match than the specially selected matched pairs available from Mullard a decade or two ago. If only they'd been available when I blew £25 of 1985 hard-earned pocket money on a matched pair of EL34s when I got my first valve guitar amp out of the disposal pile at school ;-)

Since the instructions are pretty straightforward and the only thing you're unlikely to have is a suitable plastic screwdriver. On my TS-520 the neutralising trimmer was incredibly stiff. With the power off and PA supply discharged I spun it a few times with a steel screwdriver with an insulated shaft until 30-odd years of dried-up grease was spread around the cap bush. Then I trimmed and filed a thick acrylic knitting needle to a screwdriver point, and used that to adjust the neutralising as per the book.

I use an oscilloscope, hooked up with a PL259-to-BNC, 10base-2 T-piece and terminator and a short BNC cable (I knew I kept that old 10base-2 junk around for a reason). As I trimmed the neutralising, I also listened on my TH-F7E. The null was actually pretty audible - not too sharp, but deep. It was actually easier to listen to the RX and "tune for *minimum* smoke"...

> How do you know if your neutralization is correct? You need to

Am I right in thinking that one of the symptoms of a not-quite-neutralised PA is that the PLATE and LOAD interact, and need adjusted when you increase the power after switching from TUNE to CW? Mine was doing that, and then when I re-trimmed the neutralising it didn't do it as much - but it's back to its old tricks again.

Is it possible that the properties of the PA valves change a bit when they're first used? These are new old stock, so heaven knows how long they've been sitting around.

Morning Pete,

I haven't tried 6 meters mainly because I don't have an antenna
for 6. Anyway, good luck in the contest, I'm sure it will be fun.

First, for me at least, I enjoy discussions like this. We all can
learn from one another.

My understanding of how the IF signal and BS-5 or BS-8 worked
together to produce the +/- 20Khz or +/- 100Khz display was correct.
However, for some reason I had a mental block that prevented me
from seeing the requirement for the 820 mod. Therefore, after
reviewing the signal flow, what is contained in each IF signal
at various stages, the factory IF OUT verses SM-220 IF mod, and
with Pete's responses, it became quite clear what I was missing.
I agree the 820 mod is required to be made to the 820.

Discussions such as these are what ham radio is all about. Whether
we have a mental block, can't see the woods for the trees or if it
were a snake it would have bit me as it was in my case, or for what
ever reason, we all learn from discussions of this type. There is no
shame in acknowledging a mistake and it is not about ignorance or
stupidity but rather about learning and we all learn something new
everyday, whether we realize it or not.

Thank you Pete for helping me break the mental block and allowing me
to see what I simply didn't see initially! Good job Pete!

Have a great day and good luck in the contest.

Mike W5RKL

21449. TS-830S Display blanks w/ VFO-230 in Tune mode

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-14 14:59:51 UTC
From: Dana
Topic: 21449 Message: 21449

I'm very happy I found this group. I have many questions, but my first question involves my VFO-230. Is it normal for the TS-830 display to blank in Tune mode if I am using the VFO-230? If I hit the "main" buttons on the VFO, the display returns on the 830.

Thanks for any help.

So basicly what this points to is that the finals could be sus ,I think its more than that the tubes are new driver is new and I am not getting output so what would be a good starting point to look for bar completely replace the if unit and the rf board havn't got a clue at this moment

21451. TS830 No RF out

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-14 15:04:49 UTC
From: rdmegargle
Topic: 21451 Message: 21451

TS-803S
This problem came on suddenly. The rig was working great, then the next day, I was unable to get any meter movement in Tune to peak the Drive, and low to zero RF output. The SG switch in "On"

When I start the tuning process, the only indication present is the 60 ma plate current reading. I can not get any ALC reading with the drive, or any increased RF output with the Load and Plate controls. HV readings are at 900 V

Following Mike's (W5RKL) suggestions ,
I replaced R2 ☐ R4 and R7 & R8 on the Final board (which was good advice since the values had moved out of tolerance). I also installed a new Driver Tube, replaced C7, C8 & L1 in the Final cage, triple checked the band switch alignment and replaced the cracked plastic shaft coupler.

Driver Tube Voltages
Pin/Rx/Tx
1/0/6.2
2/-42.3/0.3
7/335/297
8/246/209

Final Tube Voltages
Pin/Rx/Tx
1&4/0/0.33
3/252/237
5/-99/-55

Any additional suggestions? Maybe finals?

Russ K8AF

Hello Barry,

I assume your statement of no ALC indication is in TUNE mode.
Since ALC is not used or indicated on the meter in CW mode, tuning
the 520 in CW mode requires using the IP meter setting. Place
the MODE switch in CW, flip the SEND switch UP and adjust the
DRIVE control for a peak indication on the meter. If a CW key
is plugged into the rear CW socket, pull that plug before flipping
the SEND switch UP. If you are able to tune the 520 in CW mode for
full output then I recommend the following:

Check R5 and R6 on the HV UNIT. If these resistors are bad, way
out of tolerance, the screen voltage in TUNE mode will be much lower
than it normally is in TUNE mode. This leads to very low or no ALC
indication on the meter in TUNE mode which results in the inability
to accurately tune the 520. R5 and R6 are 56K 1/2 watt resistor,
color coded Green Blue Orange. Replace them if they are out of
tolerance and check TUNE mode again.

Mike W5RKL

Hello Russ,

Check R15 and R16 on the Rectifier Unit, both are 56K 1/2 watt.
These resistor control the level of screen voltage applied to
the finals in TUNE mode. If these resistors significantly
change value, the level of final tube screen voltage can be much
less than normal in TUNE mode resulting in the symptoms you are
seeing.

No problem Mike. Hopefully all the readers came away with a better understanding as to how to interface a pan adapter display to a transceiver/receiver. I've been a pan adapter user since the "good old days". My first one was a Hallicrafters SP-44, Skyrider Panoramic. Besides the SP-44, which is still here, I have the Heath HO-13 and SB-620. I've actually mated the SB-620 with the Kenwood R-599D and it works well. The Icom 756 PRO II also has a pan display and the Flex-5000 has a super wiz-bang pan display (see a pip - click the mouse over it and you're there). Once you have and use a pan adapter, you never go back.

Mike,

I checked my high voltage board on the 520s measured the resistance on R5 and R6 R5 was 55k well yea,but I fell overbackwards R6 was and I am gobsmacked 11.90 mega ohms now I feel I am getting somewhere thanks to you mike ,all I gotta do now is order the 1/2 watters I will keep you posted to see how I get on

Barry,

You're very welcome, anytime. I'm sure once you replace R5 and R6 your
520 will work just fine. Of course that's assuming there is nothing
else wrong.

Hopefully so Pete. I have used the HO-13 with an old Mohawk RX1
receiver after modifying the RX1 for an IF output on the rear
panel. Once I performed the HO-13 alignment, it worked fine.

Have a good day Pete.

From: w5rkl
Topic: 21430 Message: 21458

Barry,

One more thing. The voltage drop across R6, at 11.9Meg, was extremely high which resulted in a significant reduction in the final tube's screen voltage in TUNE mode. As I said, replace both resistors with 56K 1/2 watt, even though only one was bad, then check the TUNE mode. Resistor's are cheap and by changing both, the voltage divider network will work as it should.

I'm sure, providing nothing else is wrong, once R5 and R6 are replaced, the 520 will work as it should. There should be more then enough drive to produce a full scale ALC meter indication in TUNE mode although I recommend no more than 3/4 peak reading in TUNE mode, controlled by the CAR control and DRIVE adjustment. When I say 3/4 scale, I do not mean the ALC meter scale. Use the top IP meter scale. Peaking the ALC in TUNE mode is a tuning aid ONLY and has nothing to do with the normal ALC indication during sideband operation.

21459. Lazy ALC meter on 10m

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-15 21:02:04 UTC
From: Neil McGrath
Topic: 21459 Message: 21459

When operating on 10m I notice that my audio distorts if I try to transmit within the normal ALC meter range. I also need to increase the mic gain to get a reading on the meter compared to other bands. The radio tunes up OK on this band and seems to work fine if I leave the mic gain set at the level I use for other bands but with hardly any ALC deflection. It seems that the ALC meter is just a bit lazy on this band. Any thoughts?

Neil

Hello Neil,

The distortion you are experiencing is not due to the lack of ALC
but rather due to over driving the speech amplifier by turning the
MIC gain setting up too high. Turn the MIC gain down and I'm sure
your output signal quality will improve significantly.

Thanks Mike. I checked R15 and R16 and they each show about 35K ohms. I'll replace them in the next day or two and report the results.

Hello Russ,

Check R15 and R16 on the Rectifier Unit, both are 56K 1/2 watt.
These resistor control the level of screen voltage applied to
the finals in TUNE mode. If these resistors significantly
change value, the level of final tube screen voltage can be much
less than normal in TUNE mode resulting in the symptoms you are
seeing.

Hello Russ,

You can tune the 830 in CW mode. Follow the same procedures as
though you were in TUNE mode except place the MODE switch in CW
and the meter switch to IP. Adjust the DRIVE control for a peak
IP meter reading followed by adjusting the PLATE control for a
dip in IP meter reading. If a significant increase in RF output
is noted then replace R15 and R16 on the Rectifier Unit.

Keep transmission times to less than 10 seconds and IP meter readings
to less than 200ma while using this method.

Mike: With the IF board in TS-820S #1 there is extremely weak receive of the calibrator in CW and TUNE modes with the set in RCVE. There is no ALC or RF output in TUNE and no RF output in CW. Everything transmits and receives as it should in LSB/USB.

Installing a good IF board from another 820S everything works just as it should in receive and all position of the MODE switch.

When using the second known good 820S, both IF boards work correctly in all modes in receive and transmit!

My known good IF board works correctly in both 820S. The "bad" IF board works correctly in the known good 820S and not correctly in the other 820S which works correctly if I insert my known good board.

Got me going around in circles.

Joe k7mks

Are the Part Numbers of the IF Board (X48-1150-XX) the same? It would also be wise to check the part numbers of the other boards that interface with the IF board through connectors IF1 through IF5. If reversing the boards in both 820's make both work properly, you could just move on. Picking and probing, and a wrong slip, could lead to a major failure. Over the years, I've learned, if I works, don't screw with it. It can be frustrating when you can't find the answer but sometimes things are like that.

21467. Re: TS-820 IF Board

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-16 16:24:03 UTC
From: w5rkl
Topic: 21461 Message: 21467

Joe,

The bad IF board is working fine in USB or LSB but not in CW/TUNE modes sounds a lot like a filter selection problem in 820 #1.

Filter selection is accomplished based on a number of things.

1. Position of plug IF2 on the IF board
2. MODE switch position
3. 14VDC present to forward bias the filter selection diodes. The filter selection diodes on the IF board are as follows:

D5 and D6 for SSB filter selection
D7 and D8 for CW filter selection

I would check the position of plug IF2 and measure the voltages as follows:

1. Mode switch set to USB or LSB, IF2 plug pins 2 or 3 should show the presence of 14VDC.

2. Mode switch set to TUNE/CW, IF2 plug pins 4 or 5 should show the presence of 14VDC.

Failure to measure 14VDC on any of the above mentioned pins will cause the appropriate filter to not be selected and can result in the symptoms you are seeing.

I installed a CW filter in a friends TS-520SE. After making the wiring changes and installing the filter, all worked fine in all modes as long as I did not select NARROW on the WIDE/NARROW switch. If NARROW was selected, receive was almost nothing and RF output was very low, not even a watt, all same symptoms as you have.

The source of the problem was a broken lead on one of the CW filter select diodes. Once I fixed that, everything worked fine.

Good point, I agree. Check the board versions.

21469. TS-820 Relays

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-16 16:46:20 UTC
From: w5rkl
Topic: 21469 Message: 21469

My 820 has a frequency stability problem that is not caused by the VFO shaft to frame connection. The stability problem results in the frequency "randomly", not all the time, jumping 3 to 5Khz up in frequency between transmit and receive. When this happens, if I briefly press the PTT button, the problem clears up. That lead me to believe the relay on the relay board could be a suspect.

I cleaned the relays, both inside and out, checked to ensure the contacts were not bent etc, but the problem is still there, again randomly.

All voltages are clean, no AC ripple, and measure what they should be.

Alignment has been performed according to the 820 service manual.

Anyone have a source other than what is in the FILES section of the forum? OMRON no longer sells that relay and MOUSER doesn't have a suggested replacement.

Mike W5RKL

Mike,
I wonder if the vibration from the relay cycling is somehow moving
another poor connection ??
I bought a relay for an 820 from someone here on the group a while back.
I think I still have it on the shelf, new in the box.
I'll look for it today.

I've actually tried that procedure with no results (except for the 60ma plate reading).

Hello Russ,

You can tune the 830 in CW mode. Follow the same procedures as
though you were in TUNE mode except place the MODE switch in CW
and the meter switch to IP. Adjust the DRIVE control for a peak
IP meter reading followed by adjusting the PLATE control for a
dip in IP meter reading. If a significant increase in RF output
is noted then replace R15 and R16 on the Rectifier Unit.

Keep transmission times to less than 10 seconds and IP meter readings
to less than 200ma while using this method.

Russ,

It has been a while since I had a TS-830 but I believe you would need to
turn on the VOX and close the CW key to make it transmit in the CW mode.

Gordon,

It's possible vibration may be causing the problem. I'll check it out
further to see what I can find. Thanks for the tip.

21474. Re: TS830 No RF out

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-16 19:16:12 UTC
From: w5rkl
Topic: 21451 Message: 21474

Then the problem may not be R15 or R16.

If receive is OK then the problem is associated with transmit only circuit(s). Check for the presence of the "TIF" frequency at the input to the RF Unit, plug 7 pin 2. If the TIF frequency is there then check for the operating frequency at the output of the double mixer, Q6 an Q7 on the RF unit, at the driver tube's grid through capacitor C69, 150pf.

Just a few suggestions.

Thanks Ken, I'll double check to make sure I'm doing this correctly. Your suggestion is greatly appreciated.--Russ

Russ,

It has been a while since I had a TS-830 but I believe you would need to
turn on the VOX and close the CW key to make it transmit in the CW mode.

From: jsloss
Topic: 21461 Message: 21477

Mike: I should have mentioned that the bad IF board worked fine in all respects, in its original 820, until the day I did a quick check before selling the radio. Then it started acting up.

Board numbers end with -53 for the good IF that works in both 820's and -43 that only in one 820. (Thanks for the board number suggestion Pete)

There is the correct USB/LSB switching voltage on IF2 pins 2/3 and TUNE/CW mode pins 4/5 when checking both IF boards.

The bad IF board worked fine once in its original 820 and now it doesnt. It does, however, work just fine in my other 820.

That perplexes me!

Thanks Gordon, I really appreciate that.

For now, I'm going to pull the CAR and PLL UNIT's, clean the
interconnecting pins and sockets, clean and check all the
connecting plugs and pins, clean all chassis grounds and tighen
all mounting screws then check the output again. There might be an
intermittent connection there some where that is causing the problem.
At the moment, I do not believe the VFO is contributing to the
problem but it's easy enough to check.

Always fun to work on the hybrids, they can really work the old
gray matter. Will let you know what I find.

Again, thank you Gordon.

Evening Gordon,

I completed the cleaning of the PLL and CAR Units and it appears
the 820 is stable. Tapping on the cabinet or the VFO housing doesn't
cause any frequency shifting or warble.

It's possible that both CAR and PLL Units had dirty interconnecting
pins. I'm going to watch it for a day or two and see if it continues
to be stable. If no further instability occurs then I won't be
needing the relay.

That is good news Mike.
Hopefully that will solve it. Dirty/loose connections seem to be the
biggest problems with these radios over years of service.
Again, if you end up needing the relay, just let me know.

21484. Extension Feet

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-17 12:45:16 UTC
From: sceneryguru
Topic: 21484 Message: 21484

Good Morning Group:

I think the subject line kind of says it all. The original part number is J02-0049-004. Kenwood was kind enough to include these in most all new equipment accessory part bags. I currently find myself with 3 UP and 2 DOWN. So the object of my request / search is for 2 sets of foot extensions to balance out the operating position.

Any constructive comments are welcome.

21485. TS830 rectifier diodes

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-17 14:05:11 UTC
From: Bopal
Topic: 21485 Message: 21485

I have been troubleshooting my 830S since it suddenly lost power output. In Xmit it shows 400V hi voltage, down from 689 in Rcv. A scope on the 800 VAC line shows a distorted waveform that appears to break down around 500V. I suspect that one or more of the diodes (D1, D2, D3, D4) are breaking down. The parts list in the service manual is not specific but I think that these are the VO8J 800 volt diodes.

I have not been able to locate a data sheet on VO8J so that I can procure a modern equivalent. Any help?

73
John, W1JGB

Pretty much any high-voltage silicon diode.

What have you got?

Hi John,

I would check the smoothing capacitors before replacing the diodes.

Mike: IF board problem corrected thanks to your comments. The "bad" IF board only had the SSB filter installed; the other "good" IF board had both SSB and CW filters. I had neglected to shift the position of the 3-wire filter connector to IF2 Position A when only the SSB filter was installed.

Many thanks for getting me thinking about filter selection. You were right on!

Hi Gordon
Just try 1N2007 diodes. They are 1000 V peak inverse voltage breakdown and 1 amp direct curent!

Don't use 1N2007 diodes. They're 560 volt, 150 mw zener diodes. 1N4007's
are probably a better choice as a rectifier replacement.
Datasheet for the V08 (J) is below. "J" determines the voltage rating.
The diode is generically called V08.
http://www.datasheetarchive.com/download/?url=http%3A%2F%2Fwww.datasheeta
rchive.com%2Fpdf-datasheets%2FDatasheets-30%2FDSA-593505.pdf
Watch for wrap-around; you might have to cut and paste into your browser.

21495. TS-530 poor receive on the low bands.

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-17 21:51:15 UTC
From: Larry
Topic: 21495 Message: 21495

I have a TS-530 I'm working on that has a weak receiver on the low bands. When I tune the coils on 1.5, 3.5, and 7, the antenna coils have no effect. The mixer coils peak as they should. I've cleaned the switch contacts several times, with no effect. Does anyone have an idea what my problem is?

21496. RE: [TS-520_820_530_830] Re: TS-830S-Neutralization question

From: Lou Blasco
Topic: 21417 Message: 21496

Hi Jim,

I wonder how you're going with the 830. A friend of mine did the repairs for the local Kenwood agent in my region of Australia. He says that in his experience you could replace the tubes in 99.9% of radios without any need to neutralize them. He did however follow the recommended procedure for tube replacement and complete the neutralization step and in most cases he found that TC-1 ended up in it's original position or very close to it.

Regards

Lou

Hello to all & Ihope this finds you well.

As has been pointed out: The HV filter caps are more to be suspected than the diodes for a sagging HV supply voltage. Ken Kemski (K4EAA.com) has replacements that fit the clamps and are electrically sound as well as well as other parts for the HV system of the hybrids. I've found his prices and service to be very good. I dont think you can go wrong by checking his web-site.

From: Jim McPhee
Topic: 21417 Message: 21498

Hi Lou,

Thanks for following up. I haven't done much since our recent discussion. Reason being that I discovered that the MFJ 949-D antenna tuner that I bought (ebay again) has a problem. It does not register any reflected power when transmitting into the G5RV antenna, so I can't determine the SWR. So, I'm holding off on things until I get a proper tuner. In the mean time, I understand that there is a good ham radio tech nearby in Albuquerque. I will track him down and ask him if he can do the neutralization process, and perhaps do an alignment as well. Eventually I would like to acquire the test equipment and the knowledge to do this myself, but now is not the time. I just got my Technician license and am studying for General class. I haven't even made a single contact yet!! I'm anxious to get on the air.

Subject: RE: [TS-520_820_530_830] Re: TS-830S-Neutralization question

Hi Jim,

I wonder how you're going with the 830. A friend of mine did the repairs for the local Kenwood agent in my region of Australia. He says that in his experience you could replace the tubes in 99.9% of radios without any need to neutralize them. He did however follow the recommended procedure for tube replacement and complete the neutralization step and in most cases he found that TC-1 ended up in it's original position or very close to it.

Hello Jim,

If the MFJ-949 is not displaying reflected power then it is quite possible the 1N34A Germanium diode in the reflected circuit is bad, burnt open. This usually occurs if the power rating of the tuner has been exceeded.

Any Germanium diode that has a voltage and current rating of 65VDC at 50ma will work. Just be sure the diode is installed properly, banded end to the circuit connection shown in the schematic. A crude drawing of a diode is shown below. Note the lead that connects to the vertical line, that is the banded end. Germanium diodes have color bands but the bands will be closest to one lead.

-------|<------ none banded lead this end

You can check the diode with an ohm meter. Connect the ohm meter leads across the diode and note the meter reading. Reverse the ohm meter leads and the ohm meter reading should be different if the diode is good. If the diode is bad, the meter will read the same regardless of how the meter leads are connected across the diode. Diodes conduct in one direction only, that's how they "rectify" AC voltage into "unfiltered pulsating" DC voltage.

Topic: 21417 Message: 21500

Mike,

Thanks! I will check that tomorrow and replace it if I find it is bad. You and many of the other folks on this forum never cease to amaze me with the breadth and depth of your knowledge!

I negotiated a discount in the price I paid for the antenna tuner, thinking it was only good as a dummy load, antenna switch and perhaps a power meter, although I'm not sure how accurate it is for that purpose.

I will let the forum know what I find out.

Regards,

Jim McPhee

Subject: [TS-520_820_530_830] Re: TS-830S-Neutralization question

Hello Jim,

If the MFJ-949 is not displaying reflected power then it is quite possible the 1N34A Germanium diode in the reflected circuit is bad, burnt open. This usually occurs if the power rating of the tuner has been exceeded.

Any Germanium diode that has a voltage and current rating of 65VDC at 50ma will work. Just be sure the diode is installed properly, banded end to the circuit connection shown in the schematic. A crude drawing of a diode is shown below. Note the lead that connects to the vertical line, that is the banded end. Germanium diodes have color bands but the bands will be closest to one lead.

-------|<------ none banded lead this end

You can check the diode with an ohm meter. Connect the ohm meter leads across the diode and note the meter reading. Reverse the ohm meter leads and the ohm meter reading should be different if the diode is good. If the diode is bad, the meter will read the same regardless of how the meter leads are connected across the diode. Diodes conduct in one direction only, that's how they "rectify" AC voltage into "unfiltered pulsating" DC voltage.

Mike W5RKL

Hi. I use two 1" square blocks of wood painted flat black under the
feet of my TS-530S. I did not get the extension feet with it. If 1" is
too much, I an sure you can find something at a home improvement store.
Maybe some PVC or copper pipe caps could have a hole drilled and be
painted black.

I currently find myself with 3 UP and 2 DOWN. So the object of my request / search is for 2 sets of foot extensions to balance out the operating position.

I think you meant 1N4007, there is a 1N2007 but the package is strange.
If you want something bomb proof try a 1N5408, 3A, 1000V, watch the lead
diameter as the leads are 1.5mm in diameter, compared to 0.8 mm for a
1N4007. They both cost next to nothing.

Have a look at insulated pillars , these have threaded bushes one end
and a threaded stud the other.
they are available in various lengths, both white and black from various
suppliers, Digikey ect.
On the nut insert you can push in one of the small mushroom shaped feet.

I've actually got both, but it wasn't me that was having the problem ;-)

I use them as my "general purpose" PSU diodes in things like synthesizers, amplifiers and the like. "But why do you use a 1000V diode for a 7V power supply, Gordon?" Because a pack of 500 was a couple of quid on eBay, mostly ;-)

It would cost more to post some from the UK to the original poster than it would to buy them on eBay.

I borrowed an MFJ-949 and found that its SWR meter was pretty sensitive,
and its power meter was reasonably accurate. The actual tuner bit was a
little fiddly to use, but unless you're using a horribly mismatched
antenna (like, oh, a G5RV) you don't really need to bother much with a
hybrid rig. The pi network in the PA can deal with a pretty wide range
of mismatches - someone said about 3:1, but I don't know how accurate
that is. Certainly it has no trouble at all matching a very roughly cut
dipole for 20m.

If the correct size is chosen, rubber feet that go on the ends of canes and walkers will slide over the existing feet to extend them. These can be obtained at Ace Hardware, Wall Mart, and most drug stores.

Take a smal pvc pipe to the desire lenght and you can also add and angle to by sanding it off wa4tc

Hi. I use two 1" square blocks of wood painted flat black under the
feet of my TS-530S. I did not get the extension feet with it. If 1" is
too much, I an sure you can find something at a home improvement store.
Maybe some PVC or copper pipe caps could have a hole drilled and be
painted black.

21509. Update on my TS 830S woes

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-18 16:54:44 UTC
From: Bopal
Topic: 21509 Message: 21509

I thought that my very low power out problem was one or more blown rectifier diodes in the 800V circuit but maybe not.

While waiting the arrival of new diodes I disconnected the AC800, AC400, AC300 and AC120 lines. All measure low (~10% from nominal) and show distortion. They are not sinusoidal but halfway to trapezoidal, rounded top and bottom but nearly linear sides.

Is my transformer blown? Does anyone have DCR readings for the windings?

Hello Ted,

I know of at least 2 outlets. See below.

1. Ken, at www.k4eaa.com

or

2. Radio Shack

There may be other outlets such as Mouser Electronics, Allied
Electronics, etc.

If you choose Radio Shack, the part number is 272-1141, 12 volt 25ma
lamp. If you decide on Radio Shack and your local Radio Shack does
not have them in stock, they can order them for you and have them
shipped to your house. You pay upfront and wait 3 to 5 days for
the shipment to arrive.

John,

I do not have the DC resistance values for each winding.

A blown/bad over heated transformer has a distinct smell to it,
a smell you cannot mistake for anything else. In most cases,
not all, an overheated blown transformer will usually blow the
fuse every time power is applied to the primary.

If the transformer does not cause the fuse to blow, it doesn't
heat up simply idling (receive), then I doubt the transformers
bad.

Did you check the DC voltages at the output of the Rectifier
Unit before you disconnected the windings from the Rectifier Unit?
That would give you an indication whether the proper DC voltages are
being produced. The voltages measured at the Rectifier Unit's output
pins may vary depending on the primary AC voltage applied to the
transformer's primary windings.

This may sound silly but, did you change the transformer's primary
wiring, i.e. from 120 to 240? I'm going to assume you didn't but I
had to ask.

See the files section of this forum under "Save Your Power
Transformer" for a quick way to determine whether your transformer
is bad or not.

In following up on my other thread on this problem I checked the HV filter caps, one is bad. That is likely the problem. I have ordered a replacement from Ken at K4EAA.COM.

Thanks all. I plan to be back on the air next week.

Glad you found the culprit that is causing HV problems. I
recommend replacing "both" HV caps, not just one. I assume
you have order the "kit" from Ken, K4EAA. If so then that's
the best route to take, replace both caps.

You should also replace the 470K 1/2 watt equalizing/bleeder
resistors and the .001ufd 500VDC disc capacitors as well.

Hi to All & I hope this finds you well,

This may seem to be an obvious solution but it is the path I followed to get the angled front look for my 830. If your 830 came with all 4 stock feet on the cabinet(fore & aft) you can simply take the feet from the rear position and get the appropriate metric hardware to connect them to the front feet. I then used self-adhesive 1"X 1/2" round feet I got at Lowe's or Home Depot (I don't remember which) on the rear of the unit & I had an OEM look. It doesn't matter what kind of feet you use on the rear as long as they aren't too tall (it spoils the angled look) and as long as you use the same size feet throughout. I realize that most of the hybrids floating around have had multiple owners & yours might not have all 4 original feet, but if you find yourself with all 4 this will solve your problem. I have also seen original Kenwood feet and hardware on flea-bay but the price with shipping is usually prohibitive(not to mention unreal).

I hope I've offered a solution to some and an alternative to all;

PS up here in 8 land 10m & 6m have been very open for the last few weeks. Give it a listen & more importantly call CQ you may be pleasantly surprised.

Hello all,
I just picked up the following setup:

TS-830S Transceiver with 500hz filter
MC-50 desk mic
TS-220 Station Monitor
SP-230 Speaker with filtration
VF_240 External VFO
AT-230 Tuner
all in great condition.

I'm still in the process of reading the various manuals, but I think I found myself a pretty nice setup. Looking forward to reading the old messages in the group for tips, tricks, etc. I see that in the files section is the updated tuning procedure that everyone seemed to tell me about. Just wanted to say hello to everyone and hope to be talking to folks on the air here soon!

From: w5rkl
Topic: 21518 Message: 21521

Hello chuck,

If CW is slightly off frequency, more than likely the CAR UNIT needs aligned. The adjustment is in the 820 service manual which can be downloaded free from N6WK's website:

http://www.n6wk.com/kenwood/

The adjustment is located on page 45. However, if you have never done this type of adjustment before then may I suggest finding a local ham who has the skills. If the CAR UNIT is improperly adjusted, both transmit AND receive will be affected.

The receiver sensitivity appears to be caused by a dirty relay RL-1. This relay is located on the bottom side of the 820 between the final amplifier PC board and the rear panel. With the 820's front panel facing you and the 820 upside down, you will see a small metal enclosure between the final PC board and the rear panel. The metal enclosure must be removed to gain access to the relay. Looking down on the metal enclosure you will see 2 screws holding the enclosure to the chassis. You may have to remove the SG slide switch from the rear panel. If so, remove both screws holding the slide switch to the rear panel and gently move the switch towards the front panel. Now, remove both screws holding the metcal enclosure to the chassis and gently remove the enclosure. The relay is a plug in relay so remove it.

To clean the contacts, the outer plastic cover must be removed. This requires a small thin metal screw driver. Be careful as you could break the plastic outer cover. Once the cover is removed use contact cleaner on a piece of paper, slide the paper between the relay contacts. Make sure the contacts are not bent. You may have to do this a couple of times. Once done, use canned air to remove excess contact cleaner then replace the plastic cover. Reverse the removal steps to install the relay and SG slide switch. Check that no wires are broken or pinched between the metal enclosure and/or the SG slide switch metal housing.

If you have any further quesiton simply ask.

To: TS-520_820_530_830@yahoogroups.com
Date: Tuesday, June 16, 2009, 8:43 AM

Hello Russ,

You can tune the 830 in CW mode. Follow the same procedures as

though you were in TUNE mode except place the MODE switch in CW

and the meter switch to IP. Adjust the DRIVE control for a peak

IP meter reading followed by adjusting the PLATE control for a

dip in IP meter reading. If a significant increase in RF output

is noted then replace R15 and R16 on the Rectifier Unit.

Keep transmission times to less than 10 seconds and IP meter readings

to less than 200ma while using this method.

When in receive with the AVC 3-way switch set to "slow", the AVC action is very jumpy, not much different than when the switch is set to "fast". Any idea what the problem might be and what I should do to correct it?
TNX and 73s,

A broken wire or very poor connection from the AGC switch's
"SLOW" switch terminal that connects to the IF UNIT's "AGS"
connection can cause this problem. If the S meter is indicating
signal strength in FAST but rests at zero in OFF, then I suspect
the AGC amplifier is operating properly. What is NOT operating
properly is the "SLOW" position. Again, as I said above, a broken
connection between the AGC "SLOW" switch terminal and the IF UNIT's
"AGS" terminal will cause this to happen.

If the AGC switch were wired backwards AND assuming that "OFF"
position does what it is suppose to do and AGC amplifiers Q5 and Q6
are performing as they should, FAST setting would produce "SLOW" AGC
and SLOW setting would produce "FAST" AGC.

I suspect a broken or very poor connection between the AGC switch
"SLOW" terminal and the IF UNIT's "AGS" terminal.

From: w9oj@iquest.net
Topic: 21524 Message: 21529

Folks on another list were curious if there are any
reasonably priced replacement transistors available to
replace (or be used to build a new unit) the 2N4049
transistors used in the DC power unit of a TS-520.

Some suggested an NTE28 but Google searches show them
to be $110 which is hardly what I would call reasonable !

If you can find one, a VFO-120 is compatible, similar to the 240 but smaller and usually cheaper.

Hi Mike,
I have 4 good used 2N4048 Transistors here. According to my cross reference they and the 2N4049 both cross to the NTE-28.
How many are you looking for? I'll sell all 4 for $100.00

73,
Gordon

It's a germanium PNP power tranny. It probably has quite a high collector current and a pathetically low hFE. Since the DC lead is fused at 20A it's probably safe to assume that it can deal with a bit more than 20A although the old saying about the transistor blowing to protect the fuse may apply here ;-)

In the absence of the proper transistor and if it was my own rig, I'd be inclined to try a pair of 2N2955s on the basis that although it's a little under spec for the job it can't be far wrong. The biasing would need adjusted, probably.

I haven't tried running the TS-520 off a more modern inverter, but I suspect the RF noise would be atrocious.

Gordon 2M0YEQ

Hello Richard,

The VFO-820 will not work with the TS-530. The TS-530 requires a VFO
that operates between 5.5 and 6Mhz. The VFO-820 operates between
5 and 5.5Mhz.

Thanks for the replies. Well I figured out how to get the main dial "in line" with zero on WWV and with every 25 KHz on the calibrator. Remove the outer knob and the 0-100 KHz metal dial. This exposes the dial bearing and its mount which can easily be removed by loosening two screws. Now the internal, white main dial is held in place by a single screw. Loosen this and the main dial can be slipped by hand into adjustment. Re-tighten this screw, and then reverse the procedure to set the dial bearing, the metal dial, and the main tuning knob into place. Now everything is "true".

I dont know where you got your spec from Gordon but a 2n2955 will not
do the job
I did find this:-
http://www.mark5.co.uk/search.php
price at GBP11 roughly US$17, not sure what the min quantity is .

Hello Mike,

The NTE-28 which is a replacement for the 2N4049, has a continuous collector current rating of "60 amps". Transistors that have that current rating will be expensive.

Greetings All,
Some time ago (2 - 3 Years) I had the same problem and after looking at all the specs I found 4 Motorola transistors that I thought would do the job. Transistor is Motorola 2N2834.

I used 2 to repair the unit in my 520s and still have the other two. There was a small reduction in output power down from 115 or so to about 85 watts..but the radio is still going and is used on 12 volts quite often...just to see if it does still work mainly. It was good insurance for if the power went out.

Regards
Kevin

That's not a bad price. I'm slightly surprised that it gives the spec
as 60V, 60A - that seems a *lot* for a germanium transistor. Of course,
it might not be germanium - I'm basing that on the only site that had
any details at all which was short on real info and long on "YOU BUY NOW
BEST PRICE"-type stuff. I'd be deeply surprised if it actually *needed*
a 60A transistor.

I don't even know if the inverter on my TS-520 is working. I don't have
the right power cable for it. If anyone's got a source for a couple of
the power connectors I'd be interested.

Gordon 2M0YEQ

The power lead is fused at 20A though, so there's no way they can be running at a continuous 60A.

The manual gives the maximum power consumption as 280W. On 13.8V DC that would be a touch over 20A, so presumably it runs a little less power on DC. The power consumption in receive is given as 45W so that's 4A in receive, with a touch under 2A drawn by the valve heaters. There's just no way that the inverter transistors can be running more than a quarter of their rated current. Now, this makes sense for older parts where they maybe weren't the most reliable to begin with, but 30-odd years of developments in semiconductor technology has happened since then. You can drive modern power transistors much harder and expect them to survive.

Of course, you may be striving for originality in which case you'll want the real genuine 2N4049. They'll need replaced in pairs.

OH dear, little understanding of driving inductive loads and fuse
ratings.
Suffice to say when driving an inductive load the peak current is
substantially higher than the average. furthermore there is no such
thing as a 100% efficient inverter.
Modern designs can get close, but in the days when that inverter was
designed efficiencies where much much lower. typically 60 % if you
were lucky.

Fuses
just because it said 20A does not mean it will blow at 20A.
That is the maximum current it can handle. Steady state rupture will
occur at a much higher level.

I regularly pull 1500 A through a 100A mains fuse at work, and before you argue the UK mains fuses are not slow blow.

Finally , if the designers could have used a lower power dissipation and current rating they would have. Using overated devices was never in Japanese culture, they were used to get as many completed rigs down the production line as possible, and to keep the mtbf as high as possible. MTBF is related to first time failure rates in the factory during production, and any item that enters the repair loop in production is profit lost.

The other thing to bear in mind is where the +12V was expected to be used.
Not in the shack where is nicely regulated, but in a car.
regulators in alternators are not good at maintaining a constant voltage.
Rev up the engine with the battery disconnected, the older the vehicle the worse it gets. It will peak above 16 Volts in many cases.
And with the engine running its very spiky.

The only thing that has improved the stabilisation is the use of engine management computers, not that they regulate, but they are not able to withstand the 12 volts car supplies of the same vintage as the TS520/530 ect.

Okay, so for a maximum *input* power at the supply terminals of 280W (as given in the manual) and taking off the 45W power drawn in receive with the heaters on, that leaves a maximum of 235W input to the power supply on transmit at full chat.

Now, the manual says 160W on 3.5MHz to 21MHz input to the PA, and 140W on 28MHz. Taking 60% efficiency (let's assume the inverter is really good, as you say) then that would mean our 235W input gives about 140W output - so more or less bang on.

> Fuses

If you say so. That's not what my (admittedly 20-odd-year-old) university textbooks say. They say you shouldn't expect to run a fuse close to its rated capacity for long periods of time, but derate by 25% or more in a harsh environment.

With the battery disconnected most alternators will crank out close to 20V until the regulator fails. Not a great idea.

> The only thing that has improved the stabilisation is the use of engine
> management computers, not that they regulate, but they are not able to
> withstand the 12 volts car supplies of the same vintage as the

Oddly enough I noticed that my fiancee's '02 plate VW Polo seems to have rather *worse* regulation than my '88 Citroën CX. The CX holds a pretty steady 14.2V from about 1200rpm to the redline at 4750RPM, but the Polo can be anywhere from 11V to 15V at any speed.

We're now woefully off-topic, and I have a feeling that this is something where since you think I'm wrong and I think you're partly right but for the wrong reasons it will descend into a big argument and annoy the rest of the list. If you want to continue it I suggest we take it off-list...

Gordon

Obviously Gordon does not understand what happens when DC is applied to
an inductor.
I hope others do and realise why not to down grade Transistor ratings.

Just to add to the confusion- from my copy of the TS-520S Service Manual;

On 120/220V ac 50/60 Hz
Rx, Heaters off 26W
Rx, Heaters on 45W
Tx, (maximum) 280W

On 13.8Vdc
Rx, Heaters off 0.6A
Rx, Heaters on 5A
Tx, (maximum) 15A

DC supply 12V to 16V, 13.8V nominal.
And the dc fuse is 15A.

My TS-520S doesn't have the inverter so I can't check,
but from the circuit diagram it looks like a 'blocking oscillator'
so virtually square wave operation.
So each transistor carries up to 15A at 50% duty.

My photocopied manual has been modified to show the
transistor device type as T20A6 ... haven't checked.

A fuse should be able to carry its rated current for a very long time.
Under overload conditions it's I^2 . T that causes fuse rupture.

I've tried to keep this professional, with difficulty, When someone
asks a question if I can give an objective answer I do. When someone
gives information which will cause failure or damage to equipment I
will answer and state why.

However some people want to make a personal fight out of it.
I have been licensed since 1974 , I took the old written exam which all
amateurs at that time took, at that time there were only two classes of
licence in the UK, A & B , the only difference was a 12 wpm morse
test.Technically there was no difference between classes. I never
bothered to take the morse test as my interests were with the technical
side of the hobby and vhf to microwave. HF has never really interested
me. I bought my TS530S to see if the interest would manifest itself,
but it hasn't, it only gets switched on when I'm bored, about one log
entry a month. The licence structure has changed in the UK, the first
change was in 1975 when the written exam was replaced with a question
and answer type. So anyone with no knowledge what so ever of radio or
electronics had a 25% chance of passing. Anyone with a small amount of
knowledge that could spot the two ridiculous answers out of the four
could pass easily.
In the late 1990's a lower level exam was introduced which allowed a
lower entry to the hobby with lower power and fewer bands.
Later in the early 2000's an even lower level licence was introduced
which allowed novices with a fundamental understanding of radio to get
on air, a few hours tuition at the local radio club and a very simple

morse test.
In the UK the novice licencee can be recognised by the callsign
sequence *M3xxx.
In the last few years the morse requirement, which the previously
lowered morse requirement from 12wpm to 5, wpm was removed altogether,
so the top level licencees , either A or B.
Note you can get a Notice of variation to run 1Kw for "experimental "
use
Now the same CEPT licence covers from 136KHz to 220GHz with 400W at
the feed point.
I also work in the EMC industry designing test equipment from DC to
several GHz, I'm well qualified and I hope I have acquired a reasonable
amount of knowledge in the last 40 years since building my first radio.
I will be leaving this list, but I would like to be listed as an ELMER
for anyone requiring help

Don't.

You are no good to anyone (as an ELMER), if you aren't here to answer questions, or share your wealth of knowledge from 40 years of 'playing radio'.....

Hello,
The thing to do with microphones is TRY THEM.

When I got my TS-520S it came without a microphone
I too was looking around for a 'correct' microphone.
I tried a cheap normal moving-coil desk microphone that I had
and I've been making ssb contacts ever since!

There MAY be audio frequency response anomalies
but none of my contacts has ever commented so I assume OK.
If the RF meter moves when you speak then you are transmitting!

Having *actually tried it* rather than endlessly speculating, I can
safely say that a 600 ohm mike works with the TS520 but is a bit quiet.
There's enough gain in the mike preamp to get you just about there, but
either a high-impedance mike or one with a preamp would be better.

In short, it's not great but it's better than nothing. If all else
fails you can do frustratingly slow CW with the PTT.

My 520 *does* have the inverter but I don't have the right power lead. So, just to see what would happen I built an inverter with a spare 200W transformer and some of the MJE2955s I had kicking about. Since it has a 9-0-9-0 winding wired as 9-0-9 I used that for the primary. There is no suitable winding for the base drive, so I used capacitors from the opposite collector in a pretty traditional multivibrator circuit. The whole thing oscillates with a slightly spiky squarewave at a touch over 60Hz and has been feeding a 100W bulb with about 220V for most of the afternoon, drawing about 12A. The MJE2955s are now quite hot but nothing untoward - certainly no hotter than my 200W audio amps get after running full bore for an afternoon.

I think Richard's probably right that the MJE2955 wouldn't last terribly long driving the transformer in the TS520. I don't think there's a lot in it, though, I'm sure it wouldn't be hard to find one just a bit more suitable without forking out 100 quid apiece for 30-year-old unobtainium.

To give you an idea of how long my wait to have Ken look at my TS-830 has been, I contacted him on March 13, 2009 and asked to reserve a time to have him work on it. He told me to ship "anytime during the second weeks of May" so I shipped at the beginning of that week. The first delivery attempt was missed as no one was home to sign for it but it was delivered that Friday (5 days after shipping). I had written to him with the tracking number and delivery date right after I took it to FedEx.

I expected to hear from Ken after a few days but didn't, so on May 29th I wrote to Ken asking when he would be working on it and he replied the same day and said:

Your radio is presently #40 in the queue. But as always happens, not everyone who reserves a spot in the queue will ship in a timely fashion. That, and the sheer number of service requests is what makes it difficult to schedule accurately. Rigs on hand, scheduled before you, place your real number at about #20 - As previously released rigs continue to arrive, that could slip a bit.

I've still heard noting so it hasn't made it to his bench yet. It takes a week to ship back and a friend from the UK, who I've been trying to get interested in ham radio, is visiting on July 4th for a week so I can only hope my TS-830S will be back by then but it's not looking very hopeful that will happen.

It would have been helpful if some estimate of probable "time in the queue before alignment/repair" had been given on Ken's web site or when I was given a date to ship the transceiver to him. I naively believed I might have it back in three to four weeks.

Ken's repairs have received only the highest marks on eham.com so the wait will be worth it, I'm sure. I only wish I'd have it back to demonstrate to my UK friend. I only bought it in early March and discovered it had a couple of issues so I couldn't have requested a ship date from him any earlier.

Ive ordered parts from Ken working on my 520S and always found him reliable. Sorry your rig is taking more time to fix than you wanted. Sometimes communications get confused and the parties involved have different expectations.

My partner Grant and I repair antique tube radios from the 20's - 30's, wurlitzer and Seeburg Jukebox Amplifiers and high end stereo gear from the 70's. So we are in a similar business even though we do not work on transmitters.

When someone asks me how long will it take to fix their Cathedral radio, the only honest answer I can give them is : "About the same time it takes to catch a fish"

There are several legitimate reasons for slow service.

1. we have day jobs and lives - And I compete as an athlete. so my free time is pretty much booked.

So it not like Im sitting by the mailbox waiting for something to do. We have shelves of stuff waiting to be fixed and have to do it when we have the time.

2. Waiting for parts - we keep an inventory of common parts but its expensive to drop 70 bucks worth of capacitors into a amplifier so on hand stock isnt overly large and sometimes we have to wait for the right value to come in, especially for tubes.

3. Recapping - pretty time consuming , if you try to do a decent job. it takes time, even if you just cut leads and solder to the leads, and that looks like hell too. So to do it right you desolder and install a new part the way the company did it, much more reliable. You have to make a mechanical connection before you solder, not just tack it on and hope it holds.

3. Figuring out whats wrong - Especially hard if someones already been boogering in the unit and messed with it.

but even if its original, it takes time to go thru a circuit and check all the parts and troubleshoot it. I have a Hallicrafters SX-42 with a loose wire just floating around and will have to find where it came from before I can start work, quite a headscratcher even with schematics.

Someone had been in it and who knows what they did. The putz.

4. A lot of these units have been sitting out in the barn and are full of Dirt, mice turds and cat piss. A large amout of time is spent cleaning rusted chassis and lubrication. When I have to do veneer work, stain and Laccquer a cabinet, it takes an extra week spraying and rubbing all the coats. Lots of time is spent cleaning a unit, lubrication, mechanical repairs.

I'd go on but I start sounding like Im making whining excuses. So I wont.

The thing is, when we have a resource like Ken, who really knows his stuff, you have to give him some slack. Its not like you have

something the geek squad at best buy can handle. If Ken dosent respond to a request, send him another email, preferrably from a different email account coz a lot of the trouble is spam filtering and blocking at the email host.

Repair queues are a pain in the butt. They are difficult to manage. And the rate radios come in is generally way faster than they go out. Hopefully it will get done, but dont make plans based on any time deadlines. that way lies madness

greg

I don't have one of these mikes, but going by the PDF of the manual you want white connected to pin 1 and green and braid connected to pin four. PTT (red and black) goes to pin 2 and 3.

Now, which pin is which? Well, looking at the front of the radio, you'll see it's got four pins and a wee bump in the outer ring between the bottom two pins. The right-hand bottom pin, just right of the bump, is pin 1.

So to recap, your mike wants to be wired with white to the bottom right, braid and green to bottom left, and red and black to the top two either way round. The top right pin is grounded to transmit.

Oh, you'll want (as per endless previous discussion) the impedance set to high.

Hope this helps,

Gordon 2M0YEQ

I recently noticed while tuning my 520S that the MA gage no longer loaded to 225 as it previously did instead it tunes to 200 MA. I have replaced all the new needed components on the finals and put the new capacitors in, but I did that right after I got the radio about 6 months ago. Is this a sign the tubes are going soft. I do know that all though the reading on the gage has dropped back that the power output is about the same and it shows no sign of dropping after keyed for about five seconds in cw.

Thanks in advance

ki0gv

I'd expect the valves to last longer than six months. Have you checked your aerial and feeder? If this is something that has suddenly happened there's more likely to be a "good reason" than the valves losing emission. If you can load it up to 225mA into a dummy load, then the problem is outside your TS-520. The other day I couldn't get more than 150mA showing on the meter, and went out to find the loading coil of my 40m vertical under water. Once I'd cleared the drain at the bottom of the garden it was back to a good healthy 200mA, and as a bonus the earth spike was much more effective in the sodden ground. It's an ill wind...

Have you checked the idle current is still set to 60mA? An anode current of 200mA is still within "book figures" so if it's working well apart from that I wouldn't lose any sleep.

Saw the posts about K4EAA, I had my 530S repaired by him, I can only add the finest praise for Ken.
With that said, I now have to really part with my 530S and the matching VFO, I tried it once before but a lot of things got in the way.
Please contact me off the group, I have pictures.

Hello Allen,

I have no experience with the 940 so I cannot comment on it.

The last hybrid was the TS-830.

I use to own a TS-930. Great radio except for one major problem,
the Microprocessor Board. It failed quite often and when it did
the 930 was nothing more than a heavy metal paper weight.
The fix was to replaced the original microprocessor board with the
PIEXX Enhanced Microprocessor Board at a cost of $250. The board was
a direct drop in replacement for the original board. Took about an
hour to install it. Once installed the 930 was a really nice radio.
The new board added additional memory, dual speed tuning, serial
port rig control, and a few other features I can't remember.

The 930 also suffered from internal power supply failure. The power
supply in my 930 never failed. The only other problem my 930 had
was one of the cooling fans, the 930 has 2 on the rear panel. The
bearing dried up which caused the fan to spin at 1/2 speed and
make a lot of noise. I lubricated the fan and was able to save it.
The 930 is a great looking radio and the internal antenna
tuner was fast and quiet! I used mine primarily on CW and PSK/RTTY.
The only regret I have with the 930 is, I wish I had never sold
mine!

Hello Mike,

The 200ma you are seeing, at resonance, in CW mode is correct.
In TUNE mode, however, the IP current will be much less than in
CW mode as the final tube screen voltage is lowered in TUNE mode.

An indication of driver and/or final tubes getting weak/soft is
output drops off rapidly after tuning. Since your 520's output
appears to remain fairly constant, I seriously doubt the driver
and/or final tubes are soft.

In sideband, USB or LSB, the IP current will vary depending on the
MIC gain setting. The MIC gain controls the RF output in USB or LSB.

In TUNE and CW mode, the CAR control controls the RF output.

Sideband RF output, USB or LSB, will normally be between 20 and 30
watts on an average watt meter. This is normal and should NOT be
considered a problem with the radio. Average watt meters cannot and
will not display the 520's PEP RF output. You must use a peak reading
watt meter in order to display the 520's approximate PEP RF output.
The 520's RF meter setting indicates "relative" RF output ONLY.

Never turn the MIC gain up in order to display the PEP output
on an average watt meter. Doing so creates a lot of distortion
in the speech amplifier's output which results in your transmit
signal splattering up and down the band. Again, the only way the
approximate 520's PEP output can be displayed is by using peak
reading watt meter.

I have replaced all the new needed components on the finals and put the new capacitors in, but I did that right after I got the radio about 6 months ago. Is this a sign the tubes are going soft. I do know that all though the reading on the gage has dropped back that the power output is about the same and it shows no sign of dropping after keyed for about five seconds in cw.

Having had my TS-520S gone through and repaired by Ken about three years ago, I think there's an obvious reason yours was number 40 in the queue. He's that good, and people know it.

Unfortunately for us as customers, we had several conversations leading up to, during and after he worked on mine...and he indicated he was trying to also enjoy retirement and was doing this as much out of love for these rigs and enjoyment of working on them as for the compensation....(not that he wasn't wanting paid for his work...)

So, if someone wants repairs done in a grind-em-out large shop with in/out guaranteed dates and an invoice scale to match their overhead...he's probably not your best choice.

But, I can tell you, the work he did for me as he went through it completely and made sure everything was up to snuff after the repair was made...and the assurance I had afterwards that my rig was in as good of shape as it was the day it went out of the factory was worth the wait.

I had the choice of waiting my turn in line or fixing it myself....and I don't regret having Ken go through it and establish a baseline for me that everything was working as of dd/mm/yy date!

Topic: 11443 Message: 21570

Hello all...

For my TS520S I have bought an older CB microphone DM-2C (Albrecht). Its wiring is:
1. Audio/AF
2. GND
3. PTT RX
4. PTT TX
How should I re-organise it's wiring to suit the Kenwood's microphone socket?
And impedance 500 Ohm will work?

Thanks all for help.

Ivo, OK2SHI

Hi Ivo. The mic you have should work, although the TS-520S is
designed for a high impedance mic. In your case with the mic wired
for CB use, either the PTT RX line (button not pushed) or the PTT TX
(button pushed) is shorted to the GND wire.

To make the mic work for the Kenwood radios, you need to reconnect the
wires on the switch inside the mic so that the GND is not connected to
the switch. The PTT RX and PTT TX wires need to be wired so that they
are connected together when the button is pushed. This needs to be
done inside the microphone itself. The GND needs to be not connected
in any way to the PTT. Then wire according to the TS-520S manual.

Hi Allan.
Well the ts-930 is by fare the better radio, in my appinion. as to the last Hybrid. The 830 was i think. the TS-930 is all solide state. i will say this i have one on my desk i use every day, they come with problems, nothing that cant be fixed. a very nice radio esspecialy the RX, out performs my FT-950.
keep a look out on some of the ham outlets,RandL hamstation some times have them for a good price. i would shy away from ebay unless it's being sold by a fellow ham.
thats my 2cents

This is actually a discussion I was hoping would arise one day. I have used an 820s and now have an 830s. One of my good friends has an 850s with all of the filters and the AT. He actually likes the filtering and the bandwidth filter better on the 830s than on his 850s. I have heard wonderful things about the 850s and the 930s but have really never understood the primary differences or the relative value of either. I have considered a solid state transceiver to add but frankly have not known what to get if I were to get a Kenwood. So, the 850s or the 930s?

Feel free to reply offline if you'd like. I realize that this list is dedicated to our favorites with tube finals.

Incidentally, I may be willing to sell my 820s after field day. It's in great shape. I have both the ssb and cw filters. The cw filter has a slightly higher pitch than the normal range. Some like it higher and some don't. the original Ham used a marking tool to write his Oregon Drivers license into the side of the plastic on the transceiver, the speaker and the mic but I never see it unless I look for it. It was fully aligned about 6 months ago but I'm going to use it for field day for both cw and ssb before I let it go.

I am enjoying the 830 too much!

My TS-520S has a slightly faulty FUNCTION switch (I'll get around to fixing it one day) which can give the symptoms you described.
Try rotating the FUNCTION switch a few times.

21582. TS-830S: Time for new finals?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-23 20:09:21 UTC
From: Dana Borgman
Topic: 21582 Message: 21582

Hello All,

I am having problems with my TS-830. I just finished replacing the four 20 ohm resistors on my final board, and installed the final repair kit sold by K4EAA. I also started going through the maintenance and alignment procedures in the owner's manual. I have not done the drive coils because I don't have an alignment tool that is the right size yet.

I was just barely able to get the idle plate current to 60 mA by adjusting the bias. Today I couldn't get it higher than that -- not that I normally would want to. While trying to see what kind of power output I was getting into a dummy load by increasing the carrier, I burned up all 4 of the 20 ohm resistors on the final board with a pop. Fortunately, I expected I would do something like that and ordered extras.

Is the lack of idle plate current any indication that the finals are reaching the end? I have no problem swinging the meter in ALC mode while adjusting the drive control.

Thanks,
-- Dana, KA1WPM

Well i got the tx/rx problem fixed. had to remove a board and clean it well. the bad news is my alc drive wont hold up. even in ip on the tune falls from 225ma. so alc weak even carrier up all the way. and idle current falls from 225 ma..would the group agree time for new driver and maybee the finals as well?

21584. Burnt Band switch wafers

Date: 2009-06-23 22:06:29 UTC
From: Greg Fox
Topic: 21584 Message: 21584

After much head scratching and looking at my TS-520S I have found two damaged band switch wafers under the shield in the finals circuit at the back of the unit. Does anyone know of a compatible switch part number or a source for replacement?

Have a look at the screen grid bias, For the resistors to rapid blow,
go pop, it sounds as if the tubes where switched hard on.

The control on a tube is either by decreasing the control grid voltage,
Vg1, or by increasing the screen grid.
As you were at the limit on bias adjustment to get Ia above 60 mA, The
screen grid voltage may be low.
I suspect the screen grid feed resistors may have gone high. I don't
have a manual to check what the values should be.
But screen grid feed resistors going high with age is a very common
fault with tetrodes. Screen grid current will flow in both
directions depending on the tuning, If the resistors have gone high and
they where using the screen grid source to dump current into the screen
grid voltage rises, more gain more current into the screen grid source
and more anode current.

Its difficult to spot unless you monitor grid currents, a facility not provided by kenwood, but anyone with a big linear amp will be aware of the problem.
HTH
Some one on the list will have a manual handy for the values of the resistors.

--
Best wishes

Richard Bown

Thanks for the replies. I think I have fixed the problem by replacing C11 (a 100 uf, 16v electrolytic cap) on the Fix Channel AVR Board, This is part of the -6vdc supply. I raised the cap rating to 35v while at it. This was a suggestion in the Kenwood Service Notes list on mods.dk. Now the "Slow" AVC setting acts like it should compared to the "Fast" setting, and the S-meter is not jumping around. Thanks again.

There are a couple of 1/2W 100 ohm resistors within the PA enclosure. Being big old carbon resistors, you'll find that these have split lengthwise and now their actual resistance is anybody's guess. If the cathode resistors are in a sorry state, these grid resistors may not be far behind. You may also want to check that the screen grid voltage is changing when you switch between TUNE and the other modes

If you've changed the PA valves or if you suspect you may be boldly going where others have gone before with hobnailed boots, you should adjust the neutralising capacitor.

Check the manual carefully. The idle current should be set in
accordance with the manual to 60mA. Make sure you turn it to minimum
and increase it slowly, otherwise you risk damaging the valves or
popping the mains fuse.

When the radio is correctly tuned up you should see about 200mA on the
meter. If your aerial isn't quite well matched, you'll see somewhat
less current on the meter. Furthermore, on the higher bands you may
find that the ALC is very "peaky" and the PA is harder to tune - and you
get less power anyway.

If you can load it up and make a contact, it's working well enough.

From: w5rkl
Topic: 21583 Message: 21589

Hello Chuck,

If the ALC peaks in TUNE mode but falls off rapidly then I suspect
a weak 12BY7 driver tube.

If the problem turns out to be a weak driver tube, you do not
necessarily have to replace the finals too.

The 225ma IP current is NOT the "idling current" but rather the
final amplifier's plate current caused by amplifying the driver's
RF signal.

The final amplifier's "idling current" is the "no signal" 60ma
set by the bias pot on the rear panel in sideband mode. See the
operator's manual for details on how to set the idling current.

Although it is important to set the final amplifier's idling current
to 60ma, if it's off slightly either way, + or - a few milliamps,
the final amplifier will not be significantly affected. If you notice
this, simply follow the bias adjustment procedure outlined in the
operators manual.

When replacing final tubes, always check and, if necessary, adjust
the final amplifier bias to 60ma as outlined in the operators
manual. You do NOT have to adjust the final amplifier's bias
setting when replacing only the driver tube.

21591. 830 IF Shift issue

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-24 12:03:10 UTC
From: onefez
Topic: 21591 Message: 21591

Hi hi hi,
Sort of recently I got this 830S and noticed that the IF Shift on LSB was always fully CW for best audio, and USB was always fully CCW for "centering" the best audio. The other nite was on 20 m. and listening when I dropped to 40 m. I neglected to switch to LSB and spin the IF Shift and then lo and behold, I heard the station almost perfectly. The thing is when I did put it on LSB and then twisted the IF Shift fully CW it was fine also... So, looking at the adjustments (in service manual) I don't really see how this can be true. Also don't see how come the middle of the pot isn't doing what I think it should be doing, allowing up and down shifting of the IF. This is an old baby, serial # starts with a 1xxxxx. Is there something I am missing here, or is this all out of adjustment and needs some serious attention. I haven't done anything to it, except operate and enjoy it much more than my last rig. Any insight appreciated,
Steve

Thank you, Richard. I measured some of the resistances around the finals. It seems that, while all four cathode resistors appeared damaged, the resistance measured across them was 6.7 ohms. So, it appears that only one was destroyed.

As for the screen resistors, these measured 99.7 and 99.8 ohms, and are specified as 100 ohms. I will look at the screen bias, as you suggest. This should be 264 volts in RX and 222 volts in TX. Maybe there is something wrong with the voltage feeding those two resistors.

Cheers,
-- Dana

Gordon,

I replaced the screen resistors when I replaced the cathode resistors last week. I replaced the cathode resistors again last night. The screen resistors are still measuring 100 ohms. I had also neutralized the finals, just to be sure.

I took your advice and checked the screen voltage in TUNE and CW. Sure enough, the difference is not much. I checked R16 on the rectifier board, and it seems high, > 130 K. When I was probing voltages yesterday, I was expecting the voltage at TUN on the rectifier board to be half of SG2. It was only a little lower. So I guess the R15/R16 voltage divider is no good. I'm sure I haven't been making the finals happy while tuning, in that case.

Cheers,
-- Dana

R15 and R16 should both be 56K! if R16 has gone high then the screen grid voltage will be too high.

In general it's worth checking high value resistors that are involved in high voltage circuits on older kit. Years ago the BRC 1400 chassis was pretty common as a hand-me-down bedroom TV - all my mates had them (and I had several, in various states of repair) - where the resistor that fed the top of the brightness control went high. R119, 220k - usually found to be 1M or more. Why can I remember that, but not the PIN for the burglar alarm?

Well you will have been running the finals at more-or-less full chat while tuning. Not great, but they're tough. You won't have hurt it much.

Gordon, I have a 56K resistor in my shopping basket. Now on to the business of bias. My schematic shows that the voltage at the base of Q19 on the AF unit is controlled by the bias variable resistor. During RX, the voltage is specified as -104 volts, and during TX -59.7. I can adjust the voltage during RX to -104V. During TX, it goes to -75V, and not -59.7V as shown on the schematic. I am getting a little confused about how this voltage is supplied. I follow that the voltage across the bias variable resistor comes from VR1 and VR3, pins 1 and 3 of connector 5 on the AF unit.

VR1 comes from -C off the regulator board through R76, a 6.8K resistor on the AF Unit, correct? And this voltage should not change during TX or RX. I will check that. VR3 confuses me a bit, though. Is VR3 grounded through R78, also a 6.8K resistor, during TX? I am more confused about DRB and the source of VR3 when it is not tied to ground through R78. Can you help me sort this out? Thanks!

Hello to everyone;

Well I finally checked all resistors on the 520s HV board which were well out also the rectifier board the 470k resistor were reading a bit high 600k to 3.3mo replaced those the finals resistors ok,put everything back together hoping everything is going to be good but still no ALC,what I didn't check before when asked was checking output power set to ip /cw no output power,my bottom lip started to quiver ,a little voice in my head said the fellas on this site will put you in the right direction ,
So what would be the next step to look for I am determined to get this right myself

(footnote to the question below)

,I decided to get off my behind and do the hard yards and look myself ,The way I understand it is on tune a carrier voltage is injected through the ring modulator into the if filter right up to the driver tube on the RF board ,what I did was check the voltage before and after Q1 before it enter the 12by7a voltage before on tp2 -4.3 idle send switch on 2.5volts as per diagram after Q1 on TP1 voltage idle 14.9v send switch up 14.4v the diagram says 3.3 but it looks like 13.3v can anybody correct this ,if the voltage is 3.3 then could Q1 be causing the output problems what do you think

Hello Barry,

Have you checked the CAR UNIT's alignment yet? It's possible
the CWT signal is off frequency enough to prevent the CAR signal
from passing through the IF UNIT filters which results in very little,
if any, mixing of the CAR signal and the VFO signal in the IF UNIT's
Q2 mixer. If this occurs, there will be no "TIF" signal to mix
on the RF UNIT with the band selected heterodyne oscillator
resulting in no operating frequency applied to the driver and
ultimately, no RF drive to the final amplifier.

Mike W5RKL

21601. TS830 HV repair kit installation

Yahoo group: TS-520_820_530_830 (2009)

From: Bopal
Topic: 21601 Message: 21601

I am in the middle of installing K4AEEE hi-v repair kit - the capacitors. It appears as if the original caps were connected to each other neg-to-neg (the cans say negative is black and there are black screws on the terminals). However, the schematic shows the caps connected pos-to-neg. Am I reading the schematic correctly?

Hello Dana,

>My schematic shows that the voltage at the base of Q19 on the AF
>unit is controlled by the bias variable resistor.

Yes.

>I am getting a little confused about how this voltage is supplied.
>I follow that the voltage across the bias variable resistor comes
>from VR1 and VR3, pins 1 and 3 of connector 5 on the AF unit.

Actually, the path the -C bias voltage takes is as follows.

Bias voltage, -C, from the Rectifier Unit is applied to the AF UNIT's
-C terminal where it is fed through R76 and out AF UNIT plug 5 pin 1
as "VR1". The VR1 bias voltage continues on to the bias pot pin 1
where it appears on the bias pot's wiper, pin 2. The bias pot's wiper,
based on its setting, applies the bias voltage to the AF UNIT
plug 8 pin 3 as VR2. VR2 bias voltage is then applied through R100 to
the base of Q19. VR2 bias voltage also appears at Q19's emitter
through resistor R101. Both Q19's emitter and bias voltage through
R101, are connected to the AF UNIT's "FG" terminal. The AF UNIT's
"FG" terminal is connected to the FINAL UNIT's "FG" terminal which
terminates at the final tube grids, pin 5, applying final tube
bias. Any change in the bias pot setting causes a change at Q19's
base and emitter, which results in a change in bias voltage on the
AF and FINAL UNIT's "FG" terminal, resulting in a change in bias
voltage applied to the final tube grids, pin 5.

At the same time, the bias voltage, VR1, flows through the bias pot
and back to the AF UNIT plug 5 pin 1 as "VR3". VR3 bias voltage
continues through R78 and R83, through diode D15, to AF UNIT plug 6
pin 5 as bias voltage "DRB". AF UNIT plug 6 pin 5 is further
connected to the RF UNIT plug 8 pin 1. The bias voltage continues
through RF UNIT resistor R34 to the driver tube's grid, pin 2.

Don't become confused by the "labeling". Bias voltage VR1, VR2, VR3,
and DRB, are "ALL" the same -C bias voltage that originated from
the Rectifier Unit's "-C" terminal and applied to the AF UNIT's
"-C" terminal! The only difference is the "labeling"!

> VR1 comes from -C off the regulator board through R76, a 6.8K
>resistor on the AF Unit, correct?

The -C voltage originates from the "Rectifier" Unit board, not a
"regulator" board. The -C voltage is fed to the AF UNIT's "-C"
terminal where it flows through R76 to AF UNIT plug 5 pin 3.

>And this voltage should not change during TX or RX.

That is correct.

> Is VR3 grounded through R78, also a 6.8K resistor, during TX?

Yes, through RL1 on the AF UNIT.

>I am more confused about DRB and the source of VR3 when it is not tied to ground through R78.

Bias voltage levels do change in transmit by providing
a ground path through R78 and AF UNIT relay RL1. The original -C
voltage does NOT change, only the voltage drop changes that occurs
in the circuit due to the changes in the circuit's resistance.

John,

The HV capacitors are connected in "series".

The Rectifier Unit's "800" terminal, NOT the AC800 terminal,
connects to C24's positive terminal.

A short jumper wire connects C24's negative terminal to C22's
positive terminal.

The Rectifier Unit's 800 "0" terminal also connects to C22's
positive terminal.

The negative terminal of C22 connects to chassis ground.

Verify your wiring with the 830's schematic before applying
power, check for shorts and loose/poor solder connections to
the caps. Ensure you replace the 470K resistor and .01 disc caps.

Mike W5RKL

Hello Mike,

First of all the voltages all the the way up to pin 5 and pin 3 on the finals are correct going by the diagram,
I decided to check the carrier unit as you said,something weird is happening or I think its my understanding of whats happening,
in the transmitter section it says current is generated by the audio mic then its injected with a 3.395 carrier signal,now I know that for cw ,lsb,usb 3 frequencies are produced with in the same range but of slight difference,my question is should I see a carrier frequency in tune mode as I am not seeing the carrier ,when I switch to CW /TUNE I see the carrier and the frequency ,the moment I hit the send switch the carrier disappears this is on the output of the carrier board
I am kind of stuck mike untill I can understand whats the carrier unit is suppose to do in tune mode when the send switch is turned on.wheather or not this is a problem I am not sure.

Hello Barry,

Have you checked the CAR UNIT's alignment yet? It's possible
the CWT signal is off frequency enough to prevent the CAR signal
from passing through the IF UNIT filters which results in very little,
if any, mixing of the CAR signal and the VFO signal in the IF UNIT's
Q2 mixer. If this occurs, there will be no "TIF" signal to mix
on the RF UNIT with the band selected heterodyne oscillator
resulting in no operating frequency applied to the driver and
ultimately, no RF drive to the final amplifier.

on 2.5volts as per diagram after Q1 on TP1 voltage idle 14.9v send switch up 14.4v the diagram says 3.3 but it looks like 13.3v can anybody correct this ,if the voltage is 3.3 then could Q1 be causing the output problems what do you think

Hi Gang,
I used to have all the rigs 520,530,820,830 but sort of fell in love with
that TS 530.
If anyone knows someone selling one please *E* mail me direct.
I'm not worried about cosmetic conditions as long as the rig works
Will also consider a TS 830.

Hello Barry,

Yes, the carrier signal MUST be present in transmit regardless
of the mode. If the TUNE mode carrier is present in receive but
NOT in transmit, then that is why you have no ALC in TUNE mode
and no RF output, regardless of the CAR and DRIVE control settings.

I have seen this problem before and the problem turned out to
be a broken wire. You are going to have to trace the circuit
using the schematic as a guide to locate the source of the problem.
Use an ohm meter and check for continuity between points shown on
the schematic. At some point you will find the problem. Again, use
the schematic and trace the CW-T circuit.

Remove ALL power from the 520 and that includes pulling the power
plug from the wall outlet, when tracing the circuit using an
ohm meter.

I also recommend cleaning relay RL1. Relay RL1 is located on the
top left rear of the chassis under the VOX UNIT. See page 38 of
the 520S service manual for details on removing RL1. RL1 is a
plug in relay so you do not have to unsolder wires etc.

I also recommend cleaning the MODE and FUNCTION switch wafers
with contact cleaner.

21607. TS-520 Concerns

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-27 04:53:20 UTC
From: john stuart
Topic: 21607 Message: 21607

I had a problem recently with my TS-520. While transmitting on 10-meters, the radio suddenly went dead. The meter pegged full-bore, and I could smell smoke and hear a crackling sound. The tubes were very hot, so after about an hour, I tried again, and it worked ok. I suspect the radio got overheated. I was transmitting quite a bit over 100 watts. Also, the fan seems not to work very well. I don't feel any air being moved.
A few weeks ago, I replaced the tubes. I talked to a tech at Kenwood. He told me what tubes to get from RF Parts. He also told me that the these tubes did not need to be finalized. Does that sound right to u?
Well anyways, could u please point me in the right direction with the over-heating problem? Do I need a new fan?. Should I back off the output? Finalize the tubes after all?
Any advice would be greatly appreciated.
Thanks, John Stuart KD5RDY
BTW..This group ROCKS!

There are a few things that could cause this. First (and simplest), is the aerial actually connected? At both ends? Reliably? If the aerial is disconnected when you're transmitting, there's a lot of energy that has to go somewhere. If it's not going where it's meant to and heating up the ionosphere it'll find something else to heat.

The cathode resistors are 10 ohm 1W carbon resistors. They have quite a hard life tucked away under the PA valve bases. When I fired up my TS-520 it worked pretty well for a couple of days, then started showing higher and higher anode current and then popped the fuse. A quick check showed that the PA was running away and oscillating, and the cathode voltage was far higher than it should be. While trying to measure the resistance of the cathode resistors (two in parallel, so 5 ohms) one of them split in half - it had cracked along the side facing the chassis, out of site from above. From what others have said, it's probably worth just changing these on spec.

> air being moved.

The fan should move a fair bit of air. It's very quiet, but noticeable when it's on. It's not a howling Rolls-Royce Trent of a thing, just a quiet whirr. It may have seized, in which case you'll need to clean and lubricate the bearings with a little drop of sewing machine oil. Don't scoosh it with WD40, it'll get everywhere and make your shack smell of paraffin.

> A few weeks ago, I replaced the tubes. I talked to a tech at Kenwood.
> He told me what tubes to get from RF Parts. He also told me that the

I think he means 'neutralised'. They do need neutralised. The manual tells you how to do it, and it's been discussed on this list a few times. Basically there's a trimmer capacitor wired between the anode circuit and drive circuit of the PA. When this is correctly adjusted, it cancels out the internal capacitance of the two PA valves. If this isn't set correctly, the transmitter may produce all manner of strange oscillations. If they're particularly bad it will oscillate uncontrollably and overheat (not to mention the grotty signal it

produces).

The manual shows how to neutralise the PA. It's pretty simple, but do take heed of the warning not to adjust the capacitor with a metal screwdriver - it is at anode potential. You don't want to short that to the earthed metal PA cage. You also don't want to earth it through you, because there's quite enough juice there to silence your key. Leave the PA cage lid on, because the capacitance of that big earthed metal plate near the anode caps will affect it.

On my TS-520 the neutralising cap was pretty much seized solid. I discharged the HT caps, removed the PA lid and spun the cap in both directions with a metal screwdriver that had an insulated sleeve on it until it was much easier to turn, having spread the crusty old grease around the spindle bush a bit. Then I put it all back together and set the neutralising using a 6" long plastic screwdriver made from a cut and shaped acrylic knitting needle. The plastic screwdriver is important both for safety reasons and because sticking a metal screwdriver in there (even with an insulated sleeve) will affect the tuning.

> Well anyways, could u please point me in the right direction with the
> over-heating problem? Do I need a new fan?. Should I back off the

Free up that fan. You probably don't need to replace it.

> output? Finalize the tubes after all?

Definitely finalise that PA. *After* you've got the cooling fan working.

> Any advice would be greatly appreciated.
> Thanks, John Stuart KD5RDY
> BTW..This group ROCKS!

Let me just finish by saying, I'm not kidding about the voltages in the PA cage and around the valve bases. If you're at all unsure about working on this stuff, get someone who has worked on valve or hybrid radios to help, and make sure there's someone handy who can chop the power if you do zap yourself.

Good luck ;-)

mike,

Looks like I might of stumbled onto something ,I have the carrier frequency entering the generator board 3.5mhz generator frequency dsb out nothing,I checked the vfo frequency into the if board 5.5mhz so I should of seen an output sum of about approx 8.8mhz I thought I might be able to get the vfo frequency less the generator frequency on output on the IF board, but could not get it, it either designed to show an output when the generator and vfo mix or either I missed it,
But I think the problem is in the generator board,what should I check first before going step by step you think .

Hi John. What mode were you transmitting in? You should not go over about 100 watts output in CW mode (or don't go over 225 ma plate current(ip)). If you use the radio for PSK, RTTY, or other such modes, you should reduce power to about 25 watts, certainly no more than 45 to 50 watts. The fan is pretty quiet, and runs all the time. If its not running, you need to get that fixed. The smoke you smelled was probably some resisters on the bottom of the PA board. These resisters act like fuses, to protect the more expensive parts of the radio. See Ken s web site
http://www.k4eaa.com/index.html
for more info on this. These resisters will need to be replaced. Ken sells the resisters.

If by finalized, you mean neutralized, you DO need to neutralize the tubes. Another group member has already advised you on this issue, and there is info on Ken's web site about this too.

Hello Barry,

It appears you may be misunderstanding how the 520's transmit signal processing works.

First, the CAR UNIT provides the carrier signal. I'll use CW mode in my discussion.

In TUNE or CW modes, the 3.395Mhz CAR UNIT crystal is selected by the MODE switch. The output of the CAR UNIT is then fed to the GENERATOR board at the "CAR" terminal where it is applied to Q2 and ultimately to the balance modulator (D1 thru D4). The CAR control controls a DC voltage that is applied to the Balance Modulator. If the CAR control is set to minimum, the balance modulator is in its "Balanced" state resulting in "zero" RF output. If the CAR control is advanced (increased), a DC voltage is applied to the balance modulator through the GENERATOR UNIT's "BM" terminal causing an "Unbalanced" condition to occur in the balance modulator. The level of unbalance in the balance modulator is based on the position of the CAR control and determines the "level" of CAR UNIT signal that is available at the balance modulator's transformer, T1. The CAR signal flows through T1 to buffer amplifier Q1 where it is then applied to the GENERATOR UNIT's "GEN" terminal.

The CAR signal that appears at the GENERATOR UNIT's "GEN" terminal, is then fed to the IF UNIT's "GEN" terminal where it is applied to transformer T1 on the IF UNIT. The CAR signal is then fed to the crystal filters, which ever one is selected. The signal flows through the crystal filter and appears at the input to Q1. The output of Q1 on the IF UNIT is fed to Q2, the first transmitter mixer. The CAR signal is then mixed with the VFO signal, in Q2, producing an 8.3 to 8.8Mhz "TIF" signal.

The VFO signal varies from 5.000Mhz (top of ALL bands) to 5.500Mhz (bottom of ALL bands). If the VFO dial is set to "0", bottom of the band, the VFO's output will be "5.500Mhz". The CAR signal fed to Q2, in CW or TUNE mode, will be "3.395Mhz". Mixing the 5.500Mhz VFO signal with the 3.395Mhz CAR signal produces a "sum" frequency of "8.895Mhz" (3.395 + 5.500 = 8.895) which is now the "TIF" frequency. This signal is then applied to T3 on the IF UNIT. Transformer T3 has a "limited" range of frequencies that can pass through it. The range is between 8.395Mhz and 8.895Mhz. Any other frequencies are "rejected" by T3 and not allowed to pass. Since the mixing of the 5.500Mhz and 3.395Mhz signals produce a "sum" frequency of 8.895Mhz, the 8.895Mhz signal is "allowed" to pass through T3 and appear on the IF UNIT's "TIF" terminal. The VFO and CAR signals

are NOT within the frequency range of T3 so they are "rejected" and not allowed to pass through T3.

The "TIF" signal from the IF UNIT is then fed to the RF UNIT and appears on the RF UNIT's "TIF" terminal. The RF UNIT's "TIF" signal is then fed to RF UNIT's transformer T1 which is then applied to the second transmit mixer Q1. At the same time, the local heterodyne oscillator, Q6 and Q7 on the RF UNIT, feeds the band switch selected oscillator signal to the input of Q1 as well.

Lets say the band switch is set to 3.5Mhz. The RF UNIT's local heterodyne oscillator will produce an RF signal of 12.395Mhz that is fed to Q1, along with the 8.895Mhz "TIF" signal. These two signals "mix" producing the desired "operating" frequency of 3.500Mhz. The mixing process of these 2 signals produces a "SUM" and a "DIFFERENCE" frequency. The "SUM" frequency is 8.895Mhz + 12.395Mhz which equals 21.290Mhz. This is "NOT" the frequency we want. The "DIFFERENCE" frequency is 8.895Mhz - 12.395Mhz which equals "3.500Mhz" which "IS" the frequency we want.

The "DIFFERENCE" frequency resulting from mixing in Q1's output is then applied to the driver tube's input tank circuit, L2. L2 is selected by the band switch and is the tuned network for the driver tube's input. L2 is tuned to 3.5Mhz and allows the 3.5Mhz signal to be applied to the driver tube. The driver tube amplifies the 3.5Mhz signal which appears on the driver tube's plate. The output of the driver tube is then fed to coil driver tube's tank coil L2, again, selected by the band switch. The amplified 3.5Mhz signal is then applied to the RF UNIT's "DRV" terminal where it is fed to the FINAL UNIT's "DRV" terminal. The FINAL UNIT amplifies the signal and feeds it to the PI NETWORK and ultimately to the antenna.

That is how the transmit signal process occurs from start to finish. Understanding how this work is important in order to follow the flow of the signal in transmit. The same process occurs in sideband, USB or LSB, except a different crystal on the CAR UNIT is selected by the MODE switch.

You should also understand that until the balance modulator is "unbalanced", there will be zero RF output from the GENERATOR UNIT!

In CW, the CAR control unbalanced the balance modulator by apply a DC voltage. This voltage varies based on the CAR control setting.

In SSB (USB or LSB), the MIC gain control unbalances the balance modulator by varying the "audio" signal from the speech amplifier's, output, Q5 on the GENERATOR UNIT.

Hello John,

The "smell" and "crackling" that occured was caused by the final tube's "cathode" resistor, R3 and R4 in the 520 and R2 and R3 in the 520S and 520SE over heating due to excessive levels of IP current. The final tubes were overheating also due to excessive IP current flowing through the tubes.

The fan may be dirty and need cleaning and lubricating.

I recommend replacing both cathode resistor with 10 ohm 1 watt resistors. Do NOT increase the wattage of the resistors! Replace them with 1 watt 10 ohm resistors!

I also agree with the previous response, lower the IP current. In CW this is accomplished by the CAR control. In sideband, the MIC gain controls the IP current.

Mike W5RKL

Hello to everyone,

A few weeks ago I have bought my "new" TS-520S. Everything works fine it seems, except for one thing. I am tuning my rig according to Owners manual and another sources inside this group. But HV at the end of tuning cycle is above 800V (about 950V) It is something wrong with it? I tryied modified all steps, but result is the same all the time.
Thanks for any help.

Ivo, OK2SHI

This is normal : in receive you are measuring the HV without any load, not even the resting current, because the PA tubes are biased beyond cut-off. In transmit, the PA tubes draw around 225 mA of current in CW single tone full output in 50 ohm. So the drop in the indicated voltage. Let it alone, there will be no harm. 73's - Daniel, ON5PY

Thanks a lot Daniel. I was already worried that the tubes, or something else is congested.

21616. MC60A microphone

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-28 11:53:13 UTC
From: Neil McGrath
Topic: 21616 Message: 21616

Does anyone use the TS820s with a Kenwood MC60A microphone? I find that I need to switch the mic preamp on and then set the gain to around 90% of full travel for a reasonable modulation level at a comfortable speaking distance (with the mic switched to high impedance). Without the preamp I need to speak loud and close to the mic with full gain to get the same amount of modulation. Is this a typical seting for this particular mic?

With the preamp switched on, the amplifier circuit is constantly powered resulting in fairly regular battery changes. Is there a way to power the mic fron the rig or switch the preamp power via the PTT?

Neil,
I use a MC-60 with my 830S and with my 820S.
It works great without having the Pre-Amp on and the Mic control is only set at around the 9 O'Clock position on both radios.

73,
Gordon

21618. DG5 Issues

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-28 22:42:05 UTC
From: Kerry
Topic: 21618 Message: 21618

I broke out the TS-520 last night to do a little field day work after I got home. This is the first time I have had this radio on the air other than just receiving. When using it for a receiver I didn't have the DG-5 hooked up. Last night once she warmed up I noticed an interment issue with the DG-5. While tuning around the 40m band it would go from 7.199 to 7.300 and then stay in the 7.3xx range all the way to 7.400 where it would jump to 7.500. Now it didn't do this every time I scanned the band but it was pretty regular. Any ideas on what would cause this?

Kerry

21619. T-599 Problem

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-06-29 01:34:55 UTC
From: Kurt Cathcart
Topic: 21619 Message: 21619

Over the course of the last monthe, my t-599 has been developing an issue. It started intermittant at first but now it's constant and won't go away. It seem that I can tune up the radio just fine. When I key the mic the radio starts to transmit but I can't get any RF out of it. If the meter is set to IP I see the correct bias current. With the meter set to RF I see nothing. When it was intermittant, this problem would come and go with no predictability. Any suggestions?

Hello Kurt,

From your description it sounds like dirty switch contacts.
Try cleaning all the rotary switch contacts, including the meter
switch.

Hello Kerry,

Sounds like the VFO variable capacitor shaft to capacitor frame connection is dirty/corroded and needs cleaning.

To clean the VFO shaft to frame connection, remove the top cover and look at the right side of the VFO enclosure. You should see a small metal plate held to the VFO enclosure with 2 screws. Remove one screw and swing the plate so you can access the variable capacitor shaft to fram "fork" connection. Give that connection a shot of contact cleaner then rotate the VFO throughout its travel a few times. Using canned air, remove excessive contact cleaner along with the dirt/corrosion.

You also might clean all of the rotary switch contacts, band switch, function switch, etc with contact cleaner. Again, use canned air to remove contact cleaner and dirt/corrosion. This step will require removing both top and bottom covers.

Once these steps are completed, power up the 520 and check for VFO stability while tuning. If all is well, install both top and bottom covers.

Before doing any of these steps, turn the 520 OFF and remove the power plug from the wall outlet. Wait 10 minutes for the power supply filter capacitors to bleed down to zero.

Use just enough contact cleaner to do the job. Do not soak the VFO fork connection or any of the switch wafers. A little cleaner goes a long way.

Once you have completed these steps, wait 3 to 5 minutes before applying power. Contact cleaner is flammable and it only takes a small spark to ignite it. I always recommend using canned air after cleaning switches etc with contact cleaner. Walmart sells a large can of canned air which is what I use.

Hello Kurt,

I have a T-599D set of twins and had exactly the same issue with the XMTR. The problem was with the band switch contacts; nothing that a little tuner cleaner couldn't fix.

Before you proceed, I caution you about the high voltage in this chassis. Keep an eye on all High Voltage warning labels and cautions in the manual. These voltages are LETHAL! With the rig out of the case and off, spray the band switch. Gently move the switch between the individual band positions a few times from end to end. Do NOT use a lot of force and do NOT sweep fast. Then turn the rig on and carefully tune it up on LOW power. Repeat this procedure until the tuning action is smooth and non-intermittent. Slowly increase the power until smooth action is found up to about 30 Watts. At this point, you can be confident it is corrected. Reassemble the rig.

By the way, while your there, spray all of the front panel switches. Lastly, check bulbs and any thing else that might need attention while the rig is dismantled.

Good luck, Lou N2JPR

I think you're right. When the radio was more intermittant it seemed that I could move the band switch on the receiver (VFO unit) and it would all start working. Now it doesn't seem to make a difference. I might have to do a better job cleaning that switch or replace it.

Slowly increase the power until smooth action is found up to about 30 Watts. At this point, you can be confident it is corrected. Reassemble the rig.

By the way, while your there, spray all of the front panel switches. Lastly, check bulbs and any thing else that might need attention while the rig is dismantled.

Good luck, Lou N2JPR

Subject: [TS-520_820_530_830] T-599 Problem

Over the course of the last monthe, my t-599 has been developing an issue. It started intermittant at first but now it's constant and won't go away. It seem that I can tune up the radio just fine. When I key the mic the radio starts to transmit but I can't get any RF out of it. If the meter is set to

IP I see the correct bias current. With the meter set to RF I see nothing. When it was intermittant, this problem would come and go with no predictability. Any suggestions?

Thanks Mike, I will give that a try. I know I need to crack it open and clean the band switch anyway. Other than that issue it seemed to be doing ok. I really like this radio and can't wait to be able to use it on a more regular basis.

Thanks for the feedback Gordon. I will try another mic to see how it compares before I delve into the IF board.

Have you checked the impedance switch? The MC-60A is a dual
impedance microphone, 50K and 500 ohm, depending on the impedance
switch position.

Check the slide switch on the microphone, not the stand, to ensure
it is in the high impedance position (50K) when using the MC-60A
with the 820.

My TS-820S has plenty of drive on 80 and 20 meters, but none on 40, 15 and 10. The tank circuit is getting its B+ in all bandswitch positions. Any suggestions as to what might be causing this?

21630. Re: TS-820S: no drive on 40, 15 and 10 meters

Hello Bill,

Sounds like dirty interconnecting pins between the VCO
and PD UNIT PC boards located "inside" the PLL assembly. If these
pins get dirty or corroded, they affect the connections between
the PD and VCO UNIT PC boards which affect both transmit AND
receive. The PLL assembly is common to both transmit AND receive.

You didn't say so but I'm going to assume that the 820 not only
does NOT transmit on 40, 15, and 10 but it most likely does NOT
receive on 40, 15, and 10 either.

21631. Low sound volume to TS-520S external speaker?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-01 00:56:58 UTC
From: bostonkevino
Topic: 21631 Message: 21631

Hi,

My recently aquired 520S works well on internal speaker, but when plugged into a Kenwood SP-31 a also aquired the volume drops dramatically. I have to max out (10) the AF Gain knob to get the same sound volume level as AF Gain (2) on internal speaker.

The contacts look clean, wiring is not frayed or cracked into the jack connector on the rig.

I have plugged another radio (a modern Yaesu) into this SP-31 using the same plug/cord, the volume is much louder (as normally expected) with excellent sound quality - the filters work nicely on the SP-31.

Thoughts? advice and thoughts appreciated.

It possible the external speaker socket, on the rear of the 520,
is dirty and needs cleaning.

Open the top cover then plug the external speaker plug into the
520's ext speaker socket. Give the socket a shot of contact cleaner,
rotate the external speaker plug a few times then remove and insert
the external speaker plug a few times. Use canned air to remove
excess contact cleaner and wait a few minutes then power up the
520 and check the audio out to the SP-31.

I ran into a similar issue with the CW socket on my 820. After
cleaning the CW socket on the rear with contact cleaner, the problem
was eliminated.

If you do not have the SP-31 manual, you can download it free
at the following website in pdf format.

http://www.radioamateur.eu/schemi/ACC_audio/Kenwood_SP-31_user.pdf

Also, make sure the external speaker plug that is plugged
into the 520's rear ext speaker socket, has the "tip" wired to
SP-31's J2 "+" terminal and the "sleeve" is wired to J2's "-"
terminal.

Actually I have a similar problem on a 530s that I just obtained. The transceiver works fine on all bands but 12 & 10M. No drive on them. I can't tell if there is any reception since those bands have been about dead since I acquired the transceiver. I can hear normal level background noise on them however.

Can you hear the 530's "CAL" signal on 12 and 10 meters? If you
can then the receiver's working on 12 and 10 meters. You should be
able to peak the CAL signal with the DRIVE control.

Joe

No drive on some bands is usually due to dirty bandswitch wafer contacts.

Use deoxit to clean.
Apply the deoxit with a needle applicator.
Let it soax for 10-15 mins then wipe the wafer surface clean with a Q-Tip.

Topic: 21629 Message: 21637

If you have access to a frequency counter, you can check the
PLL's "VCO OUT" terminal for the following 12 and 10 meter
VCO frequencies. Each frequency indicated below varies as the
VFO is tuned/rotated.

12 meter VCO OUT frequency

33.33Mhz to 33.83Mhz (24.5)

10 meters VCO OUT frequency

36.83Mhz to 37.33Mhz (28.0)
37.33Mhz to 37.83Mhz (28.5)
37.83Mhz to 38.33Mhz (29)
38.33Mhz to 38.83Mhz (29.5)

The number is parens is the band switch setting.

If any one of these frequencies are missing then the receiver AND
transmitter will not work that specific band switch setting.
You "may" hear low volume "hissing" but that's all you will hear.
You will not hear any incoming signals or the CAL (Marker) signal.

Since the PLL UNIT is common to both transmit and receive, if one
of the VCO signals is missing, say the 28.5 VCO signal,
37.33Mhz to 37.83Mhz, then there will be no transmit or receive on
28.5 band switch setting but the other bands will work fine.

The band switch determines which VCO output frequency is made
available to the receiver and transmitter mixers. These signals
MUST be present at the transmit and receive mixer otherwise both
transmit and receive will fail.

You may also want to clean the PLL UNIT's plugs and pins then
check all mounting screws to ensure they are tight.

Also refer to the 530's operating manual to ensure that the WARC
band changes have been made to enable the WARC bands.

Hi, I have seen in a eham.net review that " QST ran a WARC-band modification article for this rig and its companion TS-820S in the early 80's. The magazine also featured an article on adapting the 'twins' for full QSK; I recommend the sidetone mod if one uses the TS-820S/R-820 combo on CW. "

By any chace or luck, does somebody have a copy of that QST article ?

Thanks for looking & 73's

Hi Steve. With the IF shift centered, when you switch between LSB and
USB, is the background atmospheric noise the
same pitch? If not, the carrier freq. adjustments need to be adjusted.
There are some openings on the bottom of the rig
which will allow adjustment of the trimmer capacitors. A decal
identifies where they are. On my TS-830S, I leave the
IF shift centered and adjust the LSB trimmer first by listening to some
chatter on the 75 meter band at night, where there
is any number of conversations, for the most natural sounding audio.
Then I tune to a band that uses USB and do the same
thing. I then tune to a portion of any band that is just noise and flip
between USB and LSB and compare the pitch of the
sounds and fine tune each trimmer to get them as close as possible and
consistent with what I perceive to be "normal"
SSB audio. I know this is a subjective way to do this because of
differences in what is normal sounding ssb audio.
It will get you close though. This will affect the quality of your
transmit audio too. You can make it more bassy or
trebley (sp?). The more scientific way to do this uses instruments to
measure frequencies.

I have tried the switch in both positions and normally use it in the 50k position. I did substitute an old CB desk microphone which certainly gives the audio the punch it needs but the audio quality is nothing like the MC60A. I will check the microphone wiring next to see if there are any problems in that department.

From: scott10k
Topic: 21631 Message: 21642

Adding to what Mike said, I had the same problem with my SP-520 plugging into the external speaker plug on my TS-520S. It turns out the speaker plug was dirty/corroded and a shot of DeOxit like Mike suggested cured the problem.

Thanks Bob,
I was not aware that the setting affected transmit also, very interesting. I need to stare at the service manual a little further in that case. I saw the freq. adjustments early in the service manual adjustments and it looks like I need to obtain a freq counter for doing this as this radio has been real dead on as far as the display is concerned. While this isn't demanding, I thought it peculiar that I needed those knob twists to line it up each time I went from band to band. Thanks for the info and 73,
N9FEZ Steve

There is a difference in the mobile supply options , with the different suffixes . Also the straight TS 520 , does not cover 160 meters .

The 520 S is an upgrade to the 520 and has modifications to the power supply and adds 160m along with DG5 connections and some minor features. The controls are a little different such as the load and tune control being upside down compared to the 520. There is also a small cosmetic difference, the indicator panel with the 3 lights in it is gray instead of white.

The 520 SE is the "economy" model (Kenwood didn't want to pay for all the hand wiring). It only has AC power and no transverter plugs or switch. Inside it is exactly the same as the S model, except it's missing the DC converter and the wiring associated with the transverter output and DC operation. Its also missing the heater switch.

Topic: 21644 Message: 21648

Actually, the 520 series never had a built in digital display.

The 520 operated 80 thru 10. RIT, 4 fixed crystal control sockets controlled by the front panel selector switch. 200 watt PEP input on sideband, 160 watts DC input on CW. Operated from 120/240VAC or from the 13.6VDC supply mounted on the rear panel.

The TS-520S had the same basic features as the 520 except 160 meters was added. Fixed channel selector was moved as an outer control along with the PLATE control. Meter switch moved to between the meter and the VFO. JJY was moved to the band switch and the original JJY push button became a 20db attenuator button. Same 200 watts PEP input on sideband, 160 watt DC input on CW.

The TS-520SE changed the heater switch to as a NARROW/WIDE filter selector switch. Operation on 13.6VDC through the optional DC converter that mounted on the rear panel.

ALL 520 models had RIT and operated from built in 120/240VAC switchable power supplies.

All would operate from a DC supply through the 13.6VDC converter. Standard on the 520 but optional on the 520S and 520SE. Plates were provided on the rear panel that covered the wiring access hole where the converter is connected to the 520S and 520SE.

All had external VFO and remote control connections available on the rear panel.

All used the 12BY7 driver tube and the Japanese S2001 in the final amplifier which are the equivalent to the 6146B.

CW filters were optional on all 520 models and required simple wiring changes when installing the CW filters.

Optional remote VFO for all 520 models was the VFO-520.

The 520 nor the 820 series would operate on the WARC bands. The WARC bands were not added until the 530 and 830.

The "AUX" band switch setting was for "receive only". The "AUX" band switch setting was added in the 520S and 520SE models.

Thanks to all for the information. I have the service manuals for a couple of the different models and will start looking for the differences that have been mentioned. I drive a Cavalier so mobile is not an option and 160 meters does not work that well where I live because there is a power line that has some leakage which really makes a mess of things on that band (and sometimes causes problems on 80 and 40 as well.)

It appears there may be a failure in the TC-5070P counter chip. Of course, that is assuming everything else is working properly.

However, I wouldn't rule out cleaning the band switch wafers with contact cleaner along with plugs and pins connecting to the counter assembly. Sometimes, simply pulling plugs followed by reinserting the plugs back into the pins can clear up problems. Can't say for sure this will fix your display problem but, just like cleaning the band switch wafers, it's worth a try.

The correct binary coded decimal value on the TC-5070P counter chip, pins 15, 14, 13, and 12 (DCBA), for 12 meters, should be "1110". See the 830's service manual, page 5 and 6 for details. A digital logic probe can show you what DCBA binary signals are present on pins 15, 14, 13, and 12 of the TC-5070P counter chip.

Hi Tim,

I had a problem recently with a frequency counter that counted correctly but displayed the wrong value. This might be happening with your set. In my case all the display control was inside the main counter chip and I was convinced the counter would end up in the round filing cabinet. With nothing to lose I re-soldered the pins on the main chip and it's been stable ever since. I'm not sure if the TC-5070 chip is in a socket or not but you might want to re-seat the chip if it's in a socket and take a real good look at the solder connections on the display board.

Good Luck

Hi, Group.

I just got a Kenwood TS 830-S "Gold" with the mic and an external VFO. As this is my first foray into the TS-830-S, am reading the manual this evening before I power it up. Will start with a dummy load and go from there.

It seems to be in great shape. I will be the 3rd owner--that I know of. I love these fine old machines, Kenwood, Collins, etc. I'm eager to see how this Kenwood compares to the K3, as I have heard good things about the TS-830.

Not much useful information in the above, I know.

Just saying "hello" (and before I ask the obvious question I will search the archives--namely, what does the "Gold" part of the model name do for me--anything?)

Hello Larry,

FB on acquiring the 830S. It is a great old rig & as a fine set of "ears". This group will be of immense help to you as you learn about the rig. Many of the members are quite expert and know how to impart that knowledge in a very gentle way.

As far as the "gold" designation of the rig there is some controversy and no firm consensus of what was included or different about this rig. For the best roundup of info on the hybrids (as well as repair parts and links) try Ken Kemski's website at K4EAA.com. He has some very useful info and adds his bit of flavor to the Gold Question. All-in-all you will be well served to visit is site. The reading is quite fascinating. I've bought parts from him for my 830 and found him to be fair & quick. The 24"X36" schematic he sells is quite a piece of wall-art and is easy on my old eyes as well.

Enjoy the radio and keep us informed as you progress with it.

Vy 73,

Mike K8SYN

21657. 520S will not transmit

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-05 04:08:28 UTC
From: aztrooper@sbcglobal.net
Topic: 21657 Message: 21657

Hi to the group. I am new to this group and am a relatively new ham. I looked for a while to find the best radio that would suit me and after trying to deal with all the menus on a Yaesu FT-897, I decided to look to the older radios. It came down to the Yaesu FT-101E or the the Kenwood TS-520S. I decided on the 520S and found a guy near me with one for sale. It works perfect and I picked up another one that would not transmit. Having a little background in electronics, (avionics tech for 4 years) I started to trouble shoot what the problem was. I found that the transmit relay would not even close using the send switch on the front panel or shorting the key pins on the mic connector. I found that Q8 and D8 on the VOX board were bad and the .01uf cap across the transmit relay coil was shorted. I took out the relay and it ohm tested to the correct value on the relay. I replaced the cap, Q8 and D8. Before turning on the receiver, I put my voltmeter on pin 14 of the VOX board and turned the receiver on. I got 13.8v but almost immediately, R16 that connects to Q8's emitter to pin 14 smoked. Q8 was replaced with a 2N3906 transistor. I checked the configuration on it before soldering it in place. Can anyone help with where I should go next? Thanks. Bob KD0EEZ ps I know, I only have a Tech license but I don't even have an antenna up yet. I'm testing the radio into an MFJ 949E dummy load. Taking my General in August.

The easy mistake to make is that D8 is the back-EMF diode across the relay coils and is therefore connected "backwards" with the cathode towards the positive supply and anode connected to ground.

With the diode the "right" way round, it will pass all the current instead of the relay coils and magic smoke will be evident.

21660. Ts-830 alignment question RX

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-05 14:00:57 UTC
From: tim_luvs_dawn
Topic: 21660 Message: 21660

I notice in the service manual is says on the IF board to adjust
L2 L3 L4 L5 L6 L7 L9 L11 No mention of L12 and i cant even find L12 on the if Board.
Owners manual is different
It says adjust L5 L6 L7 L11 L12 Again i can't find L12..What is correct procedure for adjusting the Rx?Thank's

Looking at the IF UNIT board with the front of the 830 to your left,
note the location of the AM filter slot. Look to the right of the AM
filter slot and you will find L11. Continue to the right of L11 and
the next transformer is "L12".

L11 is the last IF transformer in the receiver IF strip.

L12 is the balance detector input transformer.

I agree with Gordon. "IF" D8 was installed backwards, 2.89 amps of current would flow through R16, Q8, and D8 (13.6 / 4.7 = 2.89). That's the reason R16 instantly overheated and smoked when power was applied to the 520.

I suspect Q8 is toast and possibly D8 as well. A 2N2904 has an absolute maximum collector current rating of 200ma.

For safety sake, I would replace all 3 components, R16, Q8, and D8. Make sure D8 is installed correctly, banded lead to Q8's collector.

Mine is ser no:2010570 Could there have been a change made to the if Board?I am not kidding this one has no place anywhere for an am filter..Cw and stock ssb filter only..Two slots for cw and one slot for stock SSB Filter..

What is the number of the IF UNIT board in your 830? The 830 service manual I have indicates the IF UNIT has 2 different IF UNIT boards, X48-1290-00 for the 830S(K, W, T, and X) models and X48-1290-61 for the 830S (W) model.

Correction:

The X48-1290-61 IF UNIT board is for the "TS-830M (W)" model
not TS-830S (W).

I "fat fingered" the transistor number. It should be "2N3904" not
"2N2904". Can't seem to type today. Must be the heat...:)

From what I was told, the 2N3906 was the replacement for Q8. It is a PNP transistor. The 2N3904 is a NPN transistor. Am I mistaken on that? Bob

One other item. On the 1N60 diodes I bought, there are 2 black bands on one end with the other end being plain but the interior "wire" is red. I put the double banded end side connected to Q8's collector thinking the double band was the cathode end. Was I wrong? Bob

21672. TS-520SE: replace CW filter with narrow SSB filter?

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-05 19:28:47 UTC
From: Jeff
Topic: 21672 Message: 21672

Is it possible to remove the narrow CW filter from my TS-520SE and substitute a narrow SSB filter, and use the WIDE/NARROW switch to switch between the two during SSB operation? I know, I know...why ruin the radio by removing the CW filter... Honestly, I'm SSB 99.9% of the time, and would like to have the SSB options to help during contests.

Thanks!

73 de Jeff, KF5KWO
Helotes, TX

Bob, you are correct, it is a 2N3906. I mistyped it and didn't
correct the error on the second try... Not a good typing day for me!!

Bob, that is correct. The banded end connects to Q8's collector.
If that's how you connected the diode then there's something else
wrong.

I recommend tracing the circuit wiring starting at the VOX
UNIT's "RL" terminal. There is a shorted component, wire, or both
somewhere that's causing R16 to smoke.

Daniel,

I've done the conversion on both the R-820 and TS-820S, and am getting ready to do it to another "set". I'll be glad to help you through the procedure or answer any questions that might arise.

Under what set of circumstances does it blow the fuse?
Has it ever worked since you've had it?
Can you think of anything that could have caused it to start blowing fuses?

Thanks Gordon for replying.

It blows at startup. The radio was working nice. I cant' think of anything right now that causes the problem.

assuming you mean turning the power switch on, it blows a fuse!!!! sounds like transmormer, but check for wires pinched, are you sure the correct rated fuse is in the holder....

Hi guys,
I know this is a long shot, but... is there anyone out there in ZL or VK (or where ever) who has an SM220 monitor with the BS-8 pan-adaptor who would like to swap for a BS-5? Or maybe you have a BS-8 to sell?
Thanks,
John

As Mike said, the banded end should be the cathode. If you're unsure, check with a meter - remembering that if you're using an analogue meter, the *black* wire is *positive* on the resistance range. It's worth checking anyway, just in case the diode is faulty. Unusual, but not impossible.

The relay signal goes to the relays (really?), the AF board, the generator unit and pin 5 of the VFO socket on the back. I suppose the easiest thing to check is that there isn't anything shorting pin 5 of the VFO socket to ground.

On the AF board, the RL signal is fed through a couple of resistors to the emitter of Q5 in the audio preamp. In transmit, the RL voltage drives Q5 into cutoff, muting the audio. Since the first thing RL sees there is a 3k3 resistor we can probably not look too hard at the AF board - check for any blobs, frayed wires or conductive foreign objects, but it would be hard for a component fault to short RL to ground there.

On the generator board, the RL signal supplies power to the output amplifier for the balanced mixer. Again, you'd need multiple component faults for that to short the RL line to ground, although if D8 had failed dead short and RLT found itself grounded that might cause the fault.

The only other thing is that there are a couple of capacitors across the relay coils which - on my TS-520 at least - are disc ceramics. I'm a bit superstitious about 30-year-old disc ceramics used in hot environments, but they tend to fail leaky rather than dead short.

Sounds like a PSU problem, possibly caused by a blown rectifier. The HT rectifier uses pairs of diodes in series, to get an adequate reverse voltage. If one fails, the rest won't be far behind. Old PSU diodes tend to (in my experience) fail dead short and either blow mains fuses or emit copious amounts of magic smoke - sometimes both.

If it blows the fuse instantly at switch-on and nothing has been changed (like the voltage settings on the power plug) then the most likely thing is a power supply fault. This is the point where you need to ask yourself if you're happy about working on the insides - the HT power supply will kill you - no saving throw versus lightning, take 200hp damage - and you don't get a second chance.

If you want a quick and dirty check if it is the transformer, and only
do this if the mains voltage is 110V.
Change the mains setting on the back to 230/240V.
If the primary has shorted turns, the fuse will probably still blow, but
you should now have half the volts on the secondary windings which just
may give you time to probe around and see what voltages you have.
rectifier diodes going s/c ect.

If you were on 240V, could you use a yellow tranny to supply it with
110V for the same effect?

I read about some transistors on the AF board. Also I was looking at the service manual on c-31 electrolytic block behind the AVR board. Really not sure where to look.

Here we go again
The yellow transformer he referring to is a BRITISH STANDARD, it may be
available from Farnell/ Newark and farnell outlets world wide but its
UK stock.
The same applies to RS Components and its US subsidery. Not a lot of use
if you don't use a BS1633 mains socket

the problem is YOU, it doesn't matter what I write, YOU have always
gotta put in you little snide comments.

I've given good helpful answers, but you have always got to add
something.
I said I would leave the list, it was only after many direct e-mails
asking me to stay I did.
This is just the final straw. If you are going to make comments try
putting them in English.

Not everyone is aware that a tranny is slang for transformer, its also
slang for transvestite, among others.

So you can pontificate to your hearts content, don't bother replying
as I will be unsubscribing.

It was a perfectly serious and reasonable question. If you chose to see
it as a snide comment, then that says more about you than me.

Okay, granted, possibly a poor and confusing choice of words. It still
doesn't warrant the response you gave.

> So you can pontificate to your hearts content, don't bother replying

Suit yourself. If you fly off the handle any time someone asks you a
question, perhaps this isn't the best place for you.

Karl,
The first thing I would do would be to build the "Transformer Saver" which is decribed in the files section here on this group.
It sounds like you may have shorted Diodes on the rectifier board or a bad capacitor.
When you turn the radio on, is the Heater switch in the OFF position?

Topic: 21672 Message: 21698

International Radio used to make a 1.8 kHz filter kit for Kenwood series that used the "Dial Hold" switch to turn in on and off. I have in one of my three TS-830s and it works great. Putting in an SSB narrow filter in your CW narrow slot will need the additional momodification of accessing that filter in SSB mode plus not shifting your BFO... not a good idea.

Go to inrad.com

>From a bit of googling I found that Trio produced a 2m and a 6m transverter, the TV-502 and TV-506.

Were they any good, and are they worth trying to find? Would I be better just buying a VHF SSB radio?

I'm quite tempted by the idea of building a 70MHz transverter. At least I would only need one sweep of the dial to cover the whole band.

If the switch is damaged, that could very well be shorting to ground and blowing fuses.

I leave the heater switch on all the time, since I'm always running from the mains and rarely use my TS-520 for "receive-only" work. Imagine how annoyed you'd be if you heard some rare DX and then had to wait five minutes for the valves to heat up!

Hi Fred,

Just seen your post about the WARC conversion. Thanks for any help you can give me !!!

I don't know if you have read Bill's answer : he said this QST article I found in some posts is on a CD and could be send " as is ", I mean without scanning, etc..

If you have another method, could you please write down a brief summary of what has to be done, before trying to forward step-by-step instructions ?

I have a rather good thechincal backgound, at last I think so... I've gor my ham licence 42 years ago when I was sixteen. My dad was a TV serviceman and I fell into the magic pot when I was barely able to stand up...

I build my own SSB Tx-Rx combo back in 1969, remember myself grinding surplus FT-243 Xtals to make the sideband filter, and so on...

This was only to give you an idea of the guy on this side of the keyboard (or the screen ?).

Hi,
Yes you can find this article (TS820 WARC addition) in QST archives, if you are ARRL member, just a search in the database will give you the corresponding QST. After it's just a *.pdf files to downmoad. If you are not member I may send you a copy of this file. Just a fast mail!!!

I have a TV-502 that I used to use regularly with my TS-520 on 2m SSB. It worked pretty well, and the combo always drew rave reviews for the quality of the transmit audio. By today's standards, the receiver is a little hard of hearing, but I used a Landwehr mast mounted pre-amp in front of it and it did just fine. The output was 8 to 10 watts, and I used a brick amplifier to boost it on up to 170 watts. I had a lot of fun with it.

If you already have the 520 and the amplifer, then it's not a band investment. I wouldn't pay more than about $125 USD for it. Beware, it's hard to find the 502 with its cables.

Hello Stephen,

If's possible arcing may be occurring in your 520. You will have
to inspect the 520 both top and bottom, looking for burnt, cracked,
or overheating resistors, for example, along with bulging, physical
leakage from capacitor positive ends, and other signs of overheating
to be sure.

Cleaning the PA cage is a good idea which also includes the cooling
fan. Canned air from Walmart should be used to blow dust and dirt
from variable capacitor plates, cooling fan blades, and from inside
the PA cage.

I also recommend checking the two 10 ohm 1 watt cathode resistors
on the bottom of the final amplifier PC board. These resistors
tend to overheat when operators push the final amplifier too hard
for those few extra useless watts output. If these resistors
show signs of overheating, cracked bodies, or burnt appearance,
replace them with new 10 ohm 1 watt resistors. Do NOT increase
the wattage!

Hope this helps.

Topic: 21699 Message: 21706

Hi,

I have the tv-502 2m and the tv-506 6m transverters,
lot of fun to turn on the 520 and get on 2m or 6m ssb

I also use an older RF Concepts 2m brick with my Moxon antenna.

Copies of the manuals are in the file section for reference.

21707. D-104 mic question

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-09 23:28:30 UTC
From: Ed
Topic: 21707 Message: 21707

I have just acquired a mint condition D-104 with a TUG-9 amplified stand. The 9V battery is way past dead, & I'm wondering if I even need to use the preamplifier built into the base with my TS-820. Can I just connect the green wire from the top of the stand to the mic lead in the cord, and the yellow wire to the shield of the cord? IIRC, the mic element is a Hi-Z (it's a standard Astatic MC-320 element), so it seems to me that I can just do away with the preamp altogether.

TIA for any help you can offer,

73,

Ed, KD0BKH

21709. Question on the TS-820S

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-09 11:27:44 UTC
From: Hector Perez-Diaz
Topic: 21709 Message: 21709

Hi there folks. I have a TS-820S that I got about a month ago. The first time I fired it up after a previous check up and tubes ok, it blew off the fuse at the back while doing CW on my FIST frequency. I replaced the fuse and agin the same thing ocurred. I decided to give it a test on the Phone Bands and the radio worked ok for the rest of the time. I have to pinpoint that it was working ok on nets where I participate that just take short brakes to speak. Last night, I spent about an hour or so chatting on 15 meters with some friends. On of the guys talking to me said to me, "OM wait just a few seconds, my phone is ringing" at that point without me talking, the radio went off again. I presume the fuse at the back is gone , ill check it later after the usual honey does. But I wonde what might be causing such a malfunctioning with the blown fuse. Radio is ok on 60 amps of current and tubes are ok

Help is welcome

Hector

Hi Wim,

Ken is not out of business just very very busy. I ordered some parts from him a couple of weeks ago and got I replies within 24 hours of posting. You can contact him at this address

ken@...

His last email to me from this address was 7 days ago. See here for an explanation of his workload. http://www.k4eaa.com/rates.html

Hi Stephen,

Your 6146W's will be fine. Go to the files section and look at the item called "The 6146 Family of Tubes" which gives you an idea of the complications with changing tubes. Having said that I have 6146W's in two 520's and I know for a fact that a local Kenwood service agent here in Australia routinely used 6146W's as replacements back in the 1980's.

As you already stated, Ken uses 6146W's whenever he replaces tubes in a hybrid. I've yet to hear a bad work about Ken's work anywhere. The only thing you might notice is a little less power on the higher bands - maybe 5 to 10 watts less at 10m but the guy you're talking to won't be able to tell.

I think you can buy replacement tubes from Ken.

Hi Stephen. This subject has been debated here before. The consensus from those who know best seems to be to use 6146B or 6146W (after a certain manufacture date, but NOT to use 6146A. Also I have seen warnings NOT to use 6146 tubes made in China. I believe that there is a file in the files section of nthis group on the subject.

If you have any doubts what so ever then take the time and read Glen Zook's "The 6146 family of tubes" document located in the "files" section of this forum and also on Glen's website at:

http://k9sth.com/Page_2.html

Never assume or guess. Read the document so you get the right answers to your questions. If you still have questions or simply don't understand the document, drop Glen an e-mail. You can get his e-mail address on his website through the link provided above.

When I got my TS-520, it had no PA valves fitted and I was told by the seller to find S2001s or 6146As but definitely not 6146Bs. Now, I've seen S2001s described as an equivalent for both 6146A and 6146B, from different sources.

The chap I actually bought the valves off had two new-old-stock RCA 6146As and a driver that he'd bought for his own TS-520S but never fitted. I put them in, neutralised them according to the instructions and they've been absolutely fine. The TS-520 has seen pretty much daily use since I got it, with a lovely clean output and (as a well-known British car maker would say) adequate power.

Topic: 21710 Message: 21721

Hi Gordon. Upon reading the TS-520 manual, it states that S2001A or 6146B tubes should be used to replace a bad final tube. If you read the file (The 6146 family of tubes) in the files section of this group, you will see that the 6146 and 6146A have significant differences (from the 6146B) that make it unwise to substitute 6146 or 6146A tubes for 6146B tubes (or vice versa) in most cases. I would say that you are lucky to not have had any problems using the 6146A tubes in your TS-520.

While I have never tried to substitute 6146A tubes for 6146Bs in any Kenwood hybrid, I always listen to those with more experience and knowledge than myself. Such as Ken (K4EAA). Ken repairs and restores Kenwood hybrid radios. In the FAQ section of his web site, he recommends against the use of 6146A tubes in the Kenwood hybrid radios.

21725. TS-830s Parts / Fixer Rig for sale

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-11 20:40:45 UTC
From: Dave
Topic: 21725 Message: 21725

Hi -

It is time to clean up the shack, so I'm selling a TS-830s parts rig. This would be good for someone who works on these rigs for parts, but could probably be brought back to life with a well-stocked Kenwood junk box.

This rig has been in storage for 7-8 years since I acquired it. It was a project that never got done and I've managed to keep my other 830s on the air.

The bad:

* No tubes, but the driver shield is included
* RF board has some cracked cores in a few inductors
* Tune knob skirt is broken, all other knobs in good shape*
* Tune control shaft coupler shows a crack, but seems to be usable
* Missing the hardware (case, IF board and final cage screws) to re-assemble
* IF board is out of the rig but all wires and connectors seem to be there

Good stuff:

* No signs of arching or burns in the finals components area
* Front face in good cosmetic condition
* Almost 900v plate voltage as measured on front panel (no finals or driver, so no real tx test)
* Has top and bottom case with feet and handle. Handle looks really good, case is a bit dirty
* Trio YK-88c 500hz CW filter
* Trio YG-4555C 500hz CW filter
* Trio YK-88S1 SSB filter
* muRata CFJ455K5 IF filter
* Original 'Platnium Edition' i.e., not 'Gold' :) (see http://www.eham.net/forums/Elmers/3723)

Dave,
Would you take $150 for the unit as it is, can pay you via Paypal if you like and I will cover
the UPS shipping/insurance.

I use a Gap "Hear It" outboard noise reduction module with my TS-520. Does it work? Sometimes, on some types of noise. It does seem to reduce the atmospheric noise a bit- although not nearly as much as you would like. It does a much better job of supressing heterodynes. They probably get knocked back by 25 - 30dB. If you run the unit at the highest noise reduction settings, you start to hear quite a few artifacts from the noise reduction process. These can be just about as anoying as the noise you are hopeing to get rid of. Yet I have found that it can, under the right conditions, pull some signals out of the noise floor to the point that they are readable. But I suspect an extra 20ft. of height on my antenna would do the same or better job. I am glad I have it - it is another tool to use, but before I bought another one, I would spend a like amount of funds on antenna inprovement.

Hello Danny,

A few things to check. You may have already check these but since
you didn't say you did, thought I would mention them.

1. Check rear panel REC ANT SW. Should be in "NORMAL" position.

2. Check RF ATTN push button switch. Normal position is not depressed.

3. Can you hear the Marker signal (25Khz Function switch position)?
Adjusting the DRIVE control should cause the Marker signal to
increase in strength.

Clean the band switch wafers, all of them, with contact cleaner.
Apply contact cleaner to each band switch wafer and rotate the
switch throughout its travel a couple of times. Use canned air to
remove any/all cleaner residue.

Forgot to mention. Check the 9 pin socket on the rear panel. If
the remote VFO-520 is not being used, pins 8 and 9 must be shorted
together in order for the internal VFO to work.

The 520 came from the factory with a black 9 pin plug that shorted
pins 8 and 9. If that's being used, ensure it is fully seated in the
9 pin socket.

From: w5rkl
Topic: 21710 Message: 21740

Hello Hector,

I assume what you mean by your 520 "slides", you mean "drifting".
Do you experience the drift in receive as well?

My initial thought is the 9VDC supply on the FIX CH AVR UNIT
needs attention.

Connect a DVM's positive lead to the FIX CH AVR UNIT's terminal
labeled "9" and the negative lead to chassis ground. The voltage
should be 9VDC, +/- .1VDC. If the voltage is not correct, adjust VR1
on the FIX CH AVR UNIT so the voltage is 9VDC on the terminal labeled
"9". The VFO, both internal and external, operate from the 9VDC
supply. If it's not right, the VFO will change frequencies. The 9VDC
supply also provides power to other circuits besides the VFO.

Connect the DVM positive lead to the FIX CH AVR UNIT's "RF1" terminal
and negative lead to chassis ground. The voltage should be 3.3VDC,
+/- .1VDC. If the voltage is not right, adjust VR3 on the FIX CH AVR
UNIT so the voltage is 3.3VDC.

Also, clean all the rotary switches with contact cleaner (Band switch,
MODE switch, and FUNCTION switch).

Hello to the group

I have a weird one for you need to pick your brain,I was aligning the ts 820s and noticed after I had finished tuning ,I started to get heavy static from the receiver ,when I turned the heater switch the sound changes pitch after 15 seconds then the noise quits suddenly ,I recently replaced all the caps and tested each board before moving on to the next,the only caps not replaced yet is the smoothing caps which are on order,

I have had a good look for any broken wires and went back over the tuning I also noticed after the tune my alc is very hard to adjust its either to much or too liitle very differcult to get it right .

what do you reckon

Barry vk4baz

Topic: 21741 Message: 21742

Hello Barry,

If turning the heater switch ON and OFF causes the noise to
appear and disappear, most likely one of the tubes is arcing
internally. I suspect the driver tube.

ALC is only created when GRID CURRENT flows in the final tubes. The
only time GRID CURRENT flows in the final tubes is when the
driver's signal is sufficient to cause the final tube grids to be
"positive".

It is quite possible a bad driver tube can be causing your problem.

Hello Gary,

The bias voltage should vary on the AF UNIT and FINAL UNIT's "FG"
terminals as you adjust the bias pot in transmit. If it does NOT
then connect the volt meter to the AF UNIT's plug 8 pin 3 and
adjust the bias pot. Voltage should vary.

If the bias voltage levels vary at AF UNIT plug 8 pin 3 but not at
the "FG" terminal on the AF and FINAL UNITs when adjusting the bias
pot, then I suspect a bad Q19 on the AF UNIT.

From: Gordon
Topic: 21746 Message: 21746

I have a TS-830S here that gives me full output but shows it is running about 300ma of ip current. I am inclined to think that it might be a metering problem as the HV stays up around 800 volts under full load.If I turn the carrier control down so the meter shows 225ma, then the RF output drops down considerably.
I have checked the resistors R6 and R10 on the Finals board, they check fine. Anyone ever run into this problem?

Gordon

Hi Gordon,

I'm kind of a newbie around here, but from what I understand, if resistors R2 through R4 on the final unit are not intact, you will get a high current reading. All four in parallel should read 5 ohms.

Date: 2009-07-15 19:57:54 UTC
From: w5rkl
Topic: 21743 Message: 21750

Gary,

First, in transmit, the meter is no longer an "S" meter. The meter, in transmit, functions as an ALC, IP, RF, or HV meter, depending on the position of the meter switch. The meter functions as an "S" meter ONLY in receive.

If you have variable voltage at both AF and FINAL Unit "FG" terminals then the bias voltage should also be variable at the final tube grids, pin 5.

At this point, do not be concerned about the bias voltage level but rather the final amplifier's "IP" current. Mode switch set to USB or LSB, MIC gain turned completely CCW, and meter switch set to IP, pressing the microphone PTT or flipping the SEND switch up, the IP meter should indicate approximately 60ma. If not then adjust the bias pot and set the idling current to 60ma. The IP current scale is the top scale on the meter. The 830 has to be keyed in order for the IP meter to indicate idling current.

You're right Dana. Don't know how I overlooked that. I measured the resistors, they all measured over 35 ohms but looked perfect to the eye. I should have known that.. Senior Moment day hi hi..

Hello all,

This is my first post, i have been doing alot of reading and found some fantastic info. Im new to the kenwood scene, i did have a 940 once but that spent more time with the tech than me !!
Now ive just purchased an 830s and it has no mic, so im after something i can use on it that will be good for some ragchew.

I think its meant to have an mc-35 or mc-50 but what else is out there that will work just as well if not better than standard mics.

Also if anyone out there has a mic they dont need because you have parted out your rig and dont mind shipping to VK let me know.

Cheers.

Steve.

We do have voltage at pin 5. However we do not have voltage at pins 1 4 6 during transmit. The IP meter deflects left below 0 when PTT is pushed and bias pot has no effect. I have double and triple checked all controls to make sure they are properly set. Thanks again for all your help

Hi Steve. The original Kenwood mics are hard to beat. An MC-50 or a Shure 444 are probably your best bet for a desk mic. An MC-60 will also work. The Kenwood Hybrid radios seem to have good transmit audio with just about any decent mic. An Astatic D-104 will work also, but will need to be modified for the best sound. Also, I have found that you need a pretty quiet room to use an amplified mic. Even when turned way down, they tend to pick up the slightest sound.

if you can find the kenwood adapter model "mj-84" , you could then use the hand mike from the 940, or whatever mike you are using.

I use one here, and never any problems with it.

you could also make one by using 8 pin inline male to 4 pin with a short mike (shielded cable)

Is it OK to use an "auto tuner" matching network such as the AT-200 with vacuum tube finals on radios such as the TS-830-S--all other things being equal?

It seems to me it would not matter, but this is my first use of a tube rig, and you know what happens when we "assume."

I have been using a Realistic (radio shack) hand mic with a pre-amp in it on my TS520 .
I bought the rig new and it came without a mic. Had the hand mic in a junk box and wired it up with the 4 pin connector. It sounded ok.
It is currently in a desk drawer some where.
I'm sure it's battery is long dead. I should get it out and check the battery contacts and clean it up.
I have my Hallicrafters W9TO keyer and a J-38 connected to the 520 and use it almost every day on CW.

Yes, it's perfectly okay. Bear in mind that the PA uses a pi network to match the high impedance at the anode of the valves to the low impedance load of the antenna, which is basically a slightly special case of ATU. So, all by itself, a hybrid rig can load up into a somewhat mismatched antenna. This would be a "not quite right" antenna, rather than "entirely wrong band" antenna, though - it won't work miracles ;-)

Mike,

What I found it to be was when I purchased this rig it look like someone has had the rf board out ,when they put it back they put it back the wrong way up stream of the holding screw instead of downstream so with movement it shorted the frame onto the circuit board ,now I am worried It has blown something because my Alc is gone the driver tube is new, Thats why it sounded like arching in the receiver I only saw the sparks when moving the radio frame about thus the smell as well ,would this blow the driver tube as I replaced it twice, I am a not happy jan right now,what do you think

The type of final amplifier, solid state broadband verses
adjustable tube PI Network, has nothing to do with the type of
tuner, auto verses manual, that can be used. ALL exciter have the
same 50 to 75 ohm unbalanced coax output!

All tuners have a maximum power rating and this rating must never be
exceeded! The AT-200 has a maximum power rating of 200 watts, SSB
and CW, on HF (1.8Mhz to 30Mhz) and 100 watts on 6 meters. Therefore,
the AT-200 can be used with "any" exciter, solid state of tube type,
providing the maximum power rating is not exceeded.

The "Tune" switch on my "new" TS-830S doesn't work.

I was told I can tune it now, "as is," by lowering the "Car" setting and keying manually. Eventually I will repair the "Tune" function, but I'd like to use it for CW tonight.

As I understand it, the "Tune" switch lowers the screen grid voltage to reduce current/power in the finals.

Does the "Car" setting also adjust the screen grid, or what does it do, exactly?

I don't have a detailed schematic of the power section, just a block diagram in the owner's manual.

TIA, and pardon what I think is likely a question of basics. All my "tube" experience is in building audio (guitar) amps. So, RF "hollow state" is a new candy store for me!

21765. TS 520S for sale in S.New Hampshire

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-16 14:51:01 UTC
From: bostonkevino
Topic: 21765 Message: 21765

Hi All,

I have to make some room here in the shack (and pay for some new gear), so my TS 520S is up for grabs. Included is the transceiver and a newly installed set of 6146W's, a DG-5 digital display with cables, and an SP-31 external speaker - all are cosmetically good, and function correctly. There is no mic included in the sale.

I also have an older MFJ 949 (B series) Deluxe Versa tuner which I will include. The tuner meter has been working erratically, so it may need some TLC to get into perfect working order - it has a built-in dummy load.

I will sell for $300.00 plus cost of double boxed UPS ground shipping to anywhere in CONUS.

Please email with questions anytime - I put this on QRZ yesterday and have an offer for my asking price (minus shipping) so if no one here is interested it will likely be sold tomorrow. Payment by PayPal only.

Best, and 73!

"tune as is by varying the CAR control"

Although it is possible to tune the 830 in CW mode using the CAR control to reduce the drive to the final amplifier, advising someone to use CW mode to get around a problem is vary bad advice! I do NOT recommend using CW mode to tune the 830! If there is a problem in TUNE mode then I recommend getting it fixed before operating the 830.

Your problem appears to be caused by bad resistors R15 and R16 on the Rectifier Unit. Replacing both resistors should fix your TUNE mode problem. Of course, that's assuming everything else is working as it should.

The CAR control, controls the 830's output in TUNE and CW mode by varying a DC voltage applied to the Balance Modulator on the IF UNIT not by varying the screen voltage to the final tubes. The CAR control ONLY functions in TUNE and CW mode, NEVER in USB or LSB mode.

Barry,

I'm confused as to what your term "RF BOARD" means? Are you talking
about the RF UNIT, the board with the driver tube?

Mike,

Do you have a detailed schematic or know where I can get a service manual for the 830?

"tune as is by varying the CAR control"

Although it is possible to tune the 830 in CW mode using the CAR control to reduce the drive to the final amplifier, advising someone to use CW mode to get around a problem is vary bad advice! I do NOT recommend using CW mode to tune the 830! If there is a problem in TUNE mode then I recommend getting it fixed before operating the 830.

Your problem appears to be caused by bad resistors R15 and R16 on the Rectifier Unit. Replacing both resistors should fix your TUNE mode problem. Of course, that's assuming everything else is working as it should.

The CAR control, controls the 830's output in TUNE and CW mode by varying a DC voltage applied to the Balance Modulator on the IF UNIT not by varying the screen voltage to the final tubes. The CAR control ONLY functions in TUNE and CW mode, NEVER in USB or LSB mode.

LK,

You can download the operating and service manuals at n6wk's website:

http://www.n6wk.com/kenwood/

Simply scroll down the page and click on the link for the desired manual and high resolution 830 schematic.

The problem you described with your TS-830 is typical of R15 and R16 resistor failure on the Rectifier Unit.

Remove all power from the 830 and that includes the power cable!

The Rectifier Unit is located on the bottom of the 830.

Remove the top and bottom covers, turn the 830 upside down with the front panel facing you. You will notice the bottom of the power transformer and a PC board to the "left". The PC board is the "Rectifier Unit".

Resistors R15 and R16 are 56K 1/2 watt resistors with color bands of GREEN BLUE ORANGE. The colored bands may be difficult to read. Download the 830's service manual and turn to page 11. There you will find a picture of the Rectifier Unit in the upper right corner of the page.

R15 is mounted between the relay and terminals "SG2", "TUNE", and "14". R16 is mounted at right angles of R15 next to the relay.

I recommend replacing both resistors with new metal film resistors available at most electronic parts outlet on the Internet. I use Mouser.

If all this seems to be a big much for you to take on, find a local ham who has experience in this type of diagnosing and repair work. You don't want to mess up the board and cause more problems than you already have. There's no shame in having someone else help you fix your problem! That's how you learn, having someone show you.

Just in case my description is a bit difficult to follow,
R15 is mounted on the PC and connects between the "SG2" and "TUNE"
foil terminals. R16 is mounted to the PC board with one lead
connected to the "TUNE" PC foil and the other lead connected to the
ground foil.

21771. Need TS 830 S IF Board

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-16 21:32:50 UTC
From: dennis_tilton
Topic: 21771 Message: 21771

My trusty TS830S receive died! The problem is that L12, the 455 kH IF transformer is shorted. This can is located next to Q8.
Does anyone have an IF board they would be willing to part with?

Please let me know what you want for it and I will respond immediatly.

Thanks and 73,
Dennis AD7TV

Hi Dennis,

If you're sure that it's just a 455KHz transformer you could pull one
out of a broadcast receiver to get you going again. Also Ken K4EAA
might have replacement boards and parts. Contact him by email ken@...

"...TS-830 is typical of R15 and R16
resistor failure on the Rectifier Unit."

Thanks for the link and the detailed info from your experience, Mike.

You've probably saved me a lot of time troubleshooting. I'll let you know how it works out or if I find anything unusual, if you like. I'll probably do this tonight. I think I have those sized resistors in metal film flavor in my home shop.

Hello Bob,

Yes, providing the 4 pin microphone plug is wired properly.

If you need help wiring the D-104 and G stand, you can download
the D-104's wiring at the following website:

http://www.qsl.net/wa2mzf/d104.html

The Microphone hot and PTT hot leads should NOT share the same ground
return. Refer to the 520's operators manual for details on wiring
microphones for use with the 520.

I Never have used the "tune" setting on my TS520.except when the rig was new and I wanted to see how all the controls worked !
If you don't know how to tune a tube final, it maybe a necessary setting if you take forever to dip the plate current.
By the way, my TS520 is on it's second set of finals after nearly 40 years of daily use.

Keep in mind the loading changes at your final when you adjust the tuner will likely cause overcurrent of the final plates unless you start by lo0ading into a dummy load on CW and then turn down the carrier control until you just have enough output to see movement on your SWR meter to tune the antenna. After you have SWR tuned out, you must retune the plate and loading on the rig rig slightly (after turning the carrier control back up)./.

Yes, it's perfectly okay. Bear in mind that the PA uses a pi network to
match the high impedance at the anode of the valves to the low impedance
load of the antenna, which is basically a slightly special case of ATU.
So, all by itself, a hybrid rig can load up into a somewhat mismatched
antenna. This would be a "not quite right" antenna, rather than
"entirely wrong band" antenna, though - it won't work miracles ;-)

R.

I tuned the rig into a big old heavy Bird Termaline 50 ohms and and external wattmeter beforehand.

Maybe it's overkill, but I prefer to do them separately before loading the antenna.

I tuned/dipped the radio to a dummy load first, and then try to get the antenna reactance as low as possible with an MFJ 259B.

It seems to me the "auto tuner" (a matching network, really) is to match the impedance between the radio and the antenna, and not as a way to cheat with a bedspring antenna.

A "perfectly" resonant dipole or vertical is not necessarily 50 ohms. Thus, we have the matching network, universally known erroneously as a "tuner."

The original point of my question was whether tube finals would affect an "auto" tuner. I could not think of any reason it would matter, but felt it would be better to pose the question first.

I like this TS 830 S, especially its rx filtering and audio.

I was concerned about the loud side tones in headphones. Seems one has to access the sidetone level control from the bottom panel. Guess that was not meant to be a convenient adjustment.

Keep in mind the loading changes at your final when you adjust the tuner will likely cause overcurrent of the final plates unless you start by lo0ading into a dummy load on CW and then turn down the carrier control until you just have enough output to see movement on your SWR meter to tune the antenna. After you have SWR tuned out, you must retune the plate and loading on the rig rig slightly (after turning the carrier control back up)./.

Yes, it's perfectly okay. Bear in mind that the PA uses a pi network to match the high impedance at the anode of the valves to the low impedance load of the antenna, which is basically a slightly special case of ATU. So, all by itself, a hybrid rig can load up into a somewhat mismatched antenna. This would be a "not quite right" antenna, rather than "entirely wrong band" antenna, though - it won't work miracles ;-)

No impedance problems. The D-104 is a high impedance, 50K,
microphone and the 520 has a high impedance microphone input.

Hey, Mike

Is the D-104 (assuming it's wired properly) compatible with my TS830S?

Maybe I reach too high, but I'd like to get a hard copy or good hard copy reproduction of Service Manual.

I never have liked having to piece schematics together or read "xerox'ed" copies scanned into Adobe. Life is too short to squint.

There are some cats who make nice reproductions of service manuals and sell them (even if a bit pricey) on ebay, but they seem to have overlooked these manuals.

But if that is the biggest problem I have, then things are going well anyway, hihi.

Barry,

Then I am having a difficult time understanding how the RF UNIT can be installed incorrectly since it plugs into the COIL PACK UNIT and
can only be installed one way. In addition, the COIL PACK UNIT can
only be installed one way as well.

I have a quick question for you guys. I am getting ready to move into a new house and will finaly be getting my station set up. I have a TS-520 and will be using this as my main radio right now with some sort of ground mounted vertical.

I recently picked up a D104 with the TUG-9 amplified stand at an auction and was wondering if I should wire it up for the 520 or just use the MC-50 that I came with the radio. Can anyone tell me witch would work out better?

If it turns out the MC-50 will work better I will have that D104 either for sale or to trade for a Kenwood 2m of the same vintage as the TS-520, like the TR-7400 or something. I love the look of the old Kenwood rigs and want to build an entire station of Kenwood radios of that era and really need a 2m to access the local club repeater.

Thanks
Kerry

Hi Kerry. I would use the MC-50. I have one that works well, and
gets unsolicited comments (all good) on my TX audio with my TS-530S,
my TS-130SE, and my TS-430S (using a home built 4 pin to 8 pin
adapter). The D-104 will work, but may need a mod done to sound good.
Also, you need a quiet room to use an amplified mic.

Hello Kerry,

The amplified D-104 is a nice microphone but the amplifier in the base is cheap. I have an amplified D-104, tried it with various high impedance microphone rigs and the audio was not near as good as the non-amplified D-104s I have.

You said you wanted an entire Kenwood station. Therefore, it would stand to reason you would choose the MC-50 microphone since it is Kenwood and it was designed to be used with the 520 and other hybrids.

Keep the D-104 in the event you pick up an old vintage transmitter. The TR-7400 is a nice 2 meter FM transceiver. If you are going to use one for repeater access, I suggest you obtain an external tone encoder. The original Kenwood TR-7400 tone encoders are very difficult to find. I use a Norcomm NC-101 encoder in my 7400. Once I set the tones to 88.5hz, installed it in the 7400, it works great.

I have a quick question for you guys. I am getting ready to move into a new house and will finaly be getting my station set up. I have a TS-520 and will be using this as my main radio right now with some sort of ground mounted vertical.

I recently picked up a D104 with the TUG-9 amplified stand at an auction and was wondering if I should wire it up for the 520 or just use the MC-50 that I came with the radio. Can anyone tell me witch would work out better?

If it turns out the MC-50 will work better I will have that D104 either for sale or to trade for a Kenwood 2m of the same vintage as the TS-520, like the TR-7400 or something. I love the look of the old Kenwood rigs and want to build an entire station of Kenwood radios of that era and really need a 2m to access the local club repeater.

Thanks
Kerry

Mike,

Its not that hard to picture you have to have the 820s not a 520s in front of you to understand what I am saying ,the RF board I will call it a board for now which has the driver tube at the horizontal plane above the coil pack,this board as we all know plugs into 3 slots,if you go to the very top of the board, (finals end), you have a holding lug which holds the board in place ,its very easy for the screw to go through the lug first then the board the right way is the screw goes through the board first then the lug ,if it accidently goes the wrong way then the sharp end of the lug is very close to the circuit tracks as in my case due to moving the radio around which flexis without the covers on ,just happen touch and short itself hence the crackling and squeal in the receiver,so I hope you are following me mike my english is probably differcult,what I am worried about is I have no ALC The driver is new so I changed it just in case,

Barry,

I do not have a 520S but I do have an 820 and I'm quite familiar how the RF and COIL UNIT board mount in the 820. Unfortunately, your initial explanation didn't make sense to me but your most recent explanation does make sense.

I assume you have fixed the RF UNIT's incorrect mounting and no longer have the arcing problem. It also appears that you have replaced the driver tube.

Have you attempted to tune the 820 up in CW mode? If so, what output power does the 820 produce?

If the 820 tunes up in CW mode, have you checked the HV UNIT resistors, R5 and R6, both 56K 1/2 watt? If one or both of these resistors fail, increase significantly in resistance, there will be zero ALC indication on the meter in TUNE mode even if you can tune for full output in CW mode!

Speaking of the Astatic D104 vs. MC-50 dilemma, I'd be curious about the Shure 444.

Anyone have experience with that mic on the TS-830S?

I can't say for the 830, but for years I used a 444 with a 520 and got great audio reports. Right now I have an 820 and 520 on the bench and will try both mic with both transceivers. I'm sure they will both work equally well.

The D-104 has a characteristic harsh and tinny sound that is said to work well on SSB. It tends to punch through better. It is also very sensitive so it tends to flatten the dynamic range of the human voice like a speech compressor would.

But nice things can be said for the richer sound of an MC-50 too.

Why not use both? Perhaps the MC-50 for ragchewing and the D-104 for pile-ups and contests?

Mike W5RKL,

I have a question on my 520s. This is crazy, I get a static noise in the receive but when I re-adjust the volume control you can hear the static in the speaker go away, but quite often it will return for a while. Now when I re-adjust the volume control, I'm talking about turning it up until the static is gone and then turn it back down for normal operation. I have already replaced the control itself and that didn't do. Any Suggestions?

Thanks
ki0gv
Mike

shure 444 or better the 444d is excellent choice for any radio (for a desk mike)

d104 ug8 style is ok, bujt I stay away from any amplified mike

Hello Mike,

You might try cleaning the "Phones" AND "EXT SP" sockets. Receive audio goes through both before. Clean both even if you are using an external speaker.

Also check all PC board mounting and ground screws. Loosen the screws a half turn then tighten.

The stock MC-50 has a very characteristic "mellow" sound. It exhibits very little in the way of talk-power. However, the next time you finish a roll of toilet paper, simply take the empty cardboard tube and slip it over the MC-50 mike. Speak into or near the end of the tube. The tube opening should extend out about an inch from the front of the mike. Experimentation of the actual location may be dependent on the person speaking into the mike. The frequency response of the mike will narrow and the mike will exhibit a bit of talk power which is very handy for working DX and in contests. This mod made the rounds way back in the 70's. Location of the tube on the mike and also the length of the tube will also modify the frequency response. This is the cheap-man way to adding some zing to your MC-50 without breaking the bank.

Speaking of the Astatic D104 vs. MC-50 dilemma, I'd be curious about the Shure 444.

Anyone have experience with that mic on the TS-830S?

I have used Shure 444's on several Kenwood radios. 520-520s & 530. Good reports on all. Also used the Shure 520 (looks like 444 but has omni-directional element) and 201 hand mic.
I like the D-104's, chuck out the amp board, bypass and put a resister in line on the green audio wire. If you have a resister substitue box, that will make it easy to find out which works best for you. Use 1/4 watt, it will put more base into the mic, thus eliminating the high "raspy" sound. Good luck, Rich K8UV

I've used the 444 on Kenwood, Collins, National, Johnson, Drake, and Heath. Right now I use two on my two Drakes. I used one with the Kenwood twins as well. It worked great with all the rigs. I have used the D-104, but NEVER the amplified version. Those were mostly used for CB in order to get all the meters to peg to the right.

My thoughts only,

Hello mike and the group

The 820s was working fine until the arching was present on the RF unit with that fixed all ok,But my ALC has dispeared very little output on cw rf mode about 50 ma ,checked all resisters on the HV all appeared ok even pulled them out to check all within range,I have noticed the s meter does not register the 25khz marker on all bands either,but before everthing was adjusted within range ,I can't get the s meter to peak to S9 using the 25khz maker and adjusting vr2 on the IF unit,
Also the transformer what is the correct way to measure the voltage I am reading far less than 800v and a couple of others as well but it could be I am not doing it correctly,

I have both, plus the Heil mic. I got an onld D104 and experimented with this
http://www.qsl.net/hcara/Improving_the_D-104_N9WB_rev2.pdf
and it is a damn sight better than both the MC50 and the unmodified D104 microphone.

The D-104 has a characteristic harsh and tinny sound that is said to work
well on SSB. It tends to punch through better. It is also very sensitive
so it tends to flatten the dynamic range of the human voice like a speech
compressor would.

But nice things can be said for the richer sound of an MC-50 too.

Why not use both? Perhaps the MC-50 for ragchewing and the D-104 for
pile-ups and contests?

These rigs are up for sale as today - 07-19-2009. Cosmetically, I feel more for the ft-102. As I don't have any experience with these rigs, I would like to know if anyone had the opportunity to have them both or at least can throw a fair comparison between the two, before I make the purchase. Both rigs are in mint condition.

I am aware of the relay problems on the ft-102.

Thanks.

Hi. Personally, I would choose the Kenwood TS-830S. While I have not owned either of the radios you mention, I have owned both Kenwood and Yaesu radios from the same era, and the Kenwood radios were always superior in performance to the Yaesu radios.

Just my $10.00 ($.02 adjusted for inflation!)

has the ft-102 had its relays changed.. check mod history..

the choice really has to be yours

I find I cannot go past the MC50 as I always wanted a 60A but could not get one as I was always outbided so I bought a MC50 and had a pre amp put in it and now I would not look back as I have had some wonderful reports from local and overseas operators about the quality of the modulation from my 520S I have it set up so I can use it on two radio by means of a switch box in the middle. Dont knock the MC50

Thanks Dave and Martin for your quick response.

I've been checking all around - plenty of data on both rigs. Still looking to see if anyone has made a head to head check on both, just to make sure before I lay down the cash.

21814. Re: ts820s crackling noise coming from speaker

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-19 16:38:53 UTC
From: w5rkl
Topic: 21741 Message: 21814

Barry,

Check the AF UNIT AF1 and AF2 plugs for the following voltages:

AF1 pin 1 -- Voltage should be 9VDC
AF2 pin 6 -- Voltage should be 3.3VDC

AF1 pin 1 is the 9VDC supply that is used throughout the 820 for
both transmit and receive circuitry. If the voltage is not 9VDC,
adjust VR4 located in the middle of the AF UNIT board so the voltage
at AF1 pin 1 is 9VDC.

AF2 pin 6 is the 3.3VDC bias voltage that also is used throughout
the 820. If the voltage is not 3.3VDC, adjust VR1 located between
plugs AF1 and AF2. so the voltage at AF2 pin 6 is 3.3VDC.

Adjust the 9VDC first then adjust the 3.3VDC. The reason is the
3.3VDC is produced from the 9VDC source.

Over time the PLL and CAR UNIT assemblies interconnecting pins
have corrosion build up on the fix pins inside the metal enclosures.
This affects the PLL and CAR UNIT signals used in both transmit
and receive. To clean these pins, both the PLL UNIT and the CAR UNIT
assemblies must be removed.

Each of these assemblies consist of 2 circuit boards that interconnect
through fixed pins inside the metal enclosures. Remove each
assembly, remove the top and bottom covers, then remove each board
and clean the pins. Clean the sockets as well then install each
board back into the metal enclosure, replace the covers, and install
the assembly back into the 820. Do this to both assemblies.

I also recommend removing the relay on the RELAY UNIT, clean the
pins then remove the outer plastic cover and clean the relay contacts
with contact cleaner. Both receive and transmit control signals flow
through this relay. Corrosion can present a high resistance to
signals which can affect both transmit and receive. For example, the
"AGL" line which is the path for receiver "AGC" and transmitter "ALC"
control voltages. The "AGL" is a common path that serves both
transmit and receive gain control signals. The "AGL" line terminates
on the "IF UNIT".

The T/R relay, located on the bottom near the rear of the FINAL UNIT,
inside the small metal enclosure, does not affect the Marker
signal. The Marker signal flows directly from the MARKER UNIT to the
COIL PACK UNIT. This relay will, if carbon build up occurs on the
relay contacts, affect the receive signal. The relay is the same as

the relay on the RELAY UNIT.

Measuring the DC voltages is done at the Rectifier Unit. Voltages
can be measured elsewhere but this is the easiest way to do it.

Use the 820's service manual and measure the voltages as follows:

HV:

Positive lead to the Rectifier Unit's "800" terminal and negative
lead to the chassis.

LV:

Postive lead to 300A negative to chassis.
Positive lead to 300B negative to chassis.
Positive lead to 14 negative to chassis.

Positive lead to 210A negative to chassis.
Positive lead to 210B negative to chassis.
Positive lead to STB negative to chassis.

Bias and SG:

Negative lead to -C positive to chassis
Negative lead to SG positive to chassis

There are similar terminal labeling that have "AC" as part of the
terminal label. These are the power transformer's secondary windings.

I would not recommend adjusting the COIL PACK UNIT until a thorough
cleaning of ALL board pins, plugs, and ground connections. The PLL
and CAR UNIT assemblies, for example, are common to both transmit and
receive. If the internal interconnecting pins in each assembly are
dirty/corroded both transmit and receive will be affected.

Having owned and serviced both ,many times I would have to say the 102 when fully cleaned up,aligned and tuned correctly,has a slight edge over the 830? on receive. Transmit,no question the 102 has a cleaner signal and of course a bit more output. The 830 is MUCH easier to service and keep in peak operation. The two rigs side by side, both working? normally,you wont tell the difference in day to day operation. The 102 is not worth the premium their usually asking for them unless the rig has been gone thru my Mal and sealed. Just mu opinion.
thanks

Hi folks, Gene, WB9UOK here. Walt invited me to join the group and here I am. I have owned several of the Kenwood models that this group is about and enjoyed them. Looking at getting back on low band in the near future. I live near Walt so (whether he wants to admit it) will be asking his input on the antennas and other logistics on making that happen.

Dana,

First two digits are the manufacuring year, the second two digits are the week.

Simple, you will find this too on some condensers.

When I turn on the rig after it's been off for a few hours the vfo light comes on dim and there's no display or reception. Tapping the top of the case makes it come on and no problems when its running.Cycling the on off switch when it's been on for a while it will light up fine. Only after a few hours on inactivity that this will happen. I've checked the screws and the plug in cables and they are tight. If I turn off the agc It will power up sometimes without tapping the case. Anyone ever run across this one? 73

Hi Gordon,
The rig has a vfo socket but no plug. I don't believe the TS-530s needs one for the vfo to operate,but I could be wrong. Regards
Peter

I know my TS520 produces good quality SSB with any halfway decent mic. The quality is in the rig's circuits and anything from a 1950's tape recorder mic to a studio quality mic is going to sound good on the air. Preamps and all that CB minded crap is just a waste of money and can cause distracting background noist that takes away from your intelligablity!

Speaking of the Astatic D104 vs. MC-50 dilemma, I'd be curious about the Shure 444.

Anyone have experience with that mic on the TS-830S?

On my desk I have a TS-830 and Yaesu FT-902. Very often I compare them switching quickly the antenna.
The receiving signals strengths are the same, despite this I prefer the TS-830 because it has a better audio quality, warm and enveloping.
Moreover I think it has a little bit better selectivity.

These rigs are up for sale as today - 07-19-2009. Cosmetically, I feel more for the ft-102. As I don't have any experience with these rigs, I would like to know if anyone had the opportunity to have them both or at least can throw a fair comparison between the two, before I make the purchase. Both rigs are in mint condition.

I am aware of the relay problems on the ft-102.

Thanks.

My 530S does the exact same thing. Until I have time to look into it I'll
just keep tapping the top of the case.

Thanks Paul for replying

I decided for the TS-830. I had a deadline to get any of radios yesterday and I figure out that the ts-830 is a simpler circuit to fix.

21826. Re: RCA Tube Date Code

Yahoo group: TS-520_820_530_830 (2009)

From: Dana
Topic: 21790 Message: 21826

Wim,

Thanks for your response. Unfortunately, I don't think it will be quite so simple. The tubes themselves don't seem to have any numeric date code information on them -- only the cryptic gaps in the octagon surrounding the identification. There is the letter "F" enclosed in a square underneath the RCA logo on the base.

There is a gap in the center of the left vertical line, and a gap where the upper left diagonal meets the top horizontal line.

I tested these two tubes over the weekend. One tested "weak", and the other tested "good". Nonetheless, I hope to replace both of them tomorrow and get back on the air.

73,

21827. Re: Ts-530s question

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-20 13:14:26 UTC
From: w5rkl
Topic: 21819 Message: 21827

The 530 remote VFO socket does not have/use a jumper plug but rather
a micro switch in the remote VFO DIN socket.

The micro switch, when the remote VFO is not used, shorts pins 3
and 5 of the remote VFO socket together. This applies 9VDC from the
AF UNIT through pins 3 and 5 to power the internal VFO.

When the remote VFO is inserted into the VFO socket, pins 3 and 5
are no longer shorted together and the 9VDC supply from the AF UNIT
is routed through the DIN socket to the remote VFO's "FUNCTION". VFO
selection is controlled by the remote VFO FUNCTION switch.

The micro switch can become dirty which affects it physical movement.
When this occurs the micro switch does not always move properly
which results in intermittent shorting of pins 3 and 5 of the
remote VFO socket. Tapping on the 530's cabinet causes tapping
vibrations to "move" the micro switch allowing the switch to short
pins 3 and 5 together. I do not recommend tapping on the 530. Clean
the switch with contact cleaner.

Give the remote VFO socket a micro switch a shot of contact cleaner
then insert either the remote VFO DIN plug or a dummy DIN plug into
the VFO socket a number of time. This should fix the intermittent
problem you are experiencing.

Well it sounds like I should just keep the MC-50 and go with that. I will just put the D-104 up on the shelf for now right next to the Tuner +3 I have from my 11m SSB days. That is unless someone has a TR7400 they would like to trade for the D-104.

Kerry
KE5OFO - Weatherford Ok.

21831. 830 Plate Choke Value

Topic: 21831 Message: 21831

Does anyone know the value of the Plate choke used in the 830 and 530 radios?
I have the Part number from both manuals, but it does NOT give the value. I need a choke and thought I might just rewind one of these burnt ones. it appears to be around 200 turns on the form, but I would like to know the actual value.

thanks,
Gordon

Hello all,

I recently ordered the RK-52 resistor kit from Ken, KE4AA.
Installed resistors. However the 470 Ohm resistor has me confused as I am not sure where it goes so have not put it in. I was under the impression that it was for the Final board but looking at the Final board schematic I can not find one close or the same value to replace. I was wondering has any one else installed this kit and may know where this resitor goes. Perhaps on a different board.

Thanks for any advice.

Tripp

Gordon,
Are you referring to the parasitic suppressors?

If you're referring to L1 and L2 their values are 150uH and 470uH respectively.

If you're referring to the parasitic suppressors, no value is given, although I believe I have a notation here somewhere...

Robert

Hi Robert,

I am talking about the L1 plate Choke in the Final Cage which goes to
the Parasitic suppressors then to the Final Tube plate caps.
Not L1 on the Final Unit Board.

73,
Gordon

I thought that might be the case. Let me check my notes and see if I can find that.

Cheers,
Robert

Topic: 21741 Message: 21836

Hello mike and the group

Mike my results as asked

AF! pin 1 9.01 volts
AF2 pin6 3.31volts

HV
800v on R/B actual 923volts
LV
300a ------335volts
300b ------334volts
14v --------14.15

210a --------255v
210b --------256v
STB ---------110v

BIAS SG

-C ----------115V
SG ----------113v

I am not sure what you make of it
The carrier unit and PLL unit was totally stripped pins checked look good to me under the magifier cleaned with crc and deoxit also all the connections the both relays pulled apart and carefully cleaned ,

I just like to add one more thing I did not tell you when replacing the duel smoothing caps before I tuned everything, I wired one the caps wrong way and burnt both rectifier caps but replaced those and correctly wired 4x22 uf 450volts smoothing caps would this cause a problem ,well it caused me a headache,
I also replaced the 4 diodes d8-d10 because I was only getting 12.70volts on the af-avr unit the spec was saying between 13.5 to 15volt which seemed low but did not make much difference when replaced by 1n4004 diodes.

All I can say everything was working beautifully before I short circuited the rf unit onto the chassis

What do you make of it

Barry vk4baz

to understand what I am saying ,the RF board I will call it a board for now which has the
driver tube at the horizontal plane above the coil pack,this board as we all know plugs
into 3 slots,if you go to the very top of the board, (finals end), you have a holding lug
which holds the board in place ,its very easy for the screw to go through the lug first
then the board the right way is the screw goes through the board first then the lug ,if it
accidently goes the wrong way then the sharp end of the lug is very close to the circuit
tracks as in my case due to moving the radio around which flexis without the covers on
,just happen touch and short itself hence the crackling and squeal in the receiver,so I
hope you are following me mike my english is probably differcult,what I am worried about is
I have no ALC The driver is new so I changed it just in case,

Tripp,

Could it be on the Rectifier Unit? I have a TS-830S, and there is a 470 ohm 1 watt metal film resistor populated on that board. There is also a picture of this resistor on Ken's page explaining why not to supersize the resistors.

73,

Kerry -

I use my D-104 with my Kenwood Twins. Everybody says I have great audio. I did take out the amplifier and add the the Heil upgrade kit to it though so it's really not a D-104 any more. But if you like the style of the D-104 and the performance of Heil then that's a good way to go.

Well it sounds like I should just keep the MC-50 and go with that. I will just put the D-104 up on the shelf for now right next to the Tuner +3 I have from my 11m SSB days. That is unless someone has a TR7400 they would like to trade for the D-104.

Kerry

Kerry, You really don't need all that amplification in mics. I found one of the better mics to be a Turner 444. It has superb audio quality, but if you like the "chicken choker" style mic, replace the element with a Heil. You will really have some great quality then. Brad KB2CHY

Hi Kerry, This question has been around the globe 4-fold and it boils down to one thing and that is the prefferance of the owner/ham operator, here is what I have found.

With the MC-50 or MC-60 very good I have tried the Shure 444 and couple of other Shure mics, I even tried the D-10 and Turner amp mics, but from coast to coast and Canada and a few other places this is the report I get on the different mics.

They all have different audio quality's they all sound good but the best report I always got was the D-104 non-amplified and using the mic-gain they said gave me more drive more punch with my Kenwood this seems to be true with my Swan and Siltronix radios so it really comes down to what you like and the D-104 puts you voice tone in a range that all can hear what I mean by all can hear is some guys have a hearing loss with the human ear and the D-104 seems to help them hear me. Do a test like I did I had a friend record the qso we had one day and I would switch mics during the qso when all was said and done I liked the D-104, 2nd place was the Turner Plus-3 3rd place was the MC-60 and the others well for what I was wanting in get out my signal the D-104 won hands down.

So now it is up to you and only you it is your radio and what you want more drive, sweet sound, or a pretty mic.

Allan = kb5doh 73 & God Bless to you and yours.

Tripp,

Dana's right, there are two 470 ohm resistors on the Rectifier Unit, R5 and R6, R5 in the 300A supply and R6 in the 210A supply. If both R5 and R6 on the Rectifier Unit are good, measure 470 ohms or very close to it then you probably do not need to change either of them.

I was under the impression that it was for the Final board but looking at the Final board schematic I can not find one close or the same value to replace. I was wondering has any one else installed this kit and may know where this resitor goes. Perhaps on a different board.

21843. TS830 low voltage from transformer tap 12.6v lead

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-21 17:49:40 UTC

Topic: 21843 Message: 21843

I recently purchased a TS830 that was supposed to be in good condition. After not being able to make any contacts, I asked a local Elmer to check it out for me. I took it to him and he put it on his bench. He quickly found that it had no output on any band. He soon showed me the varnish on the inside of the bottom cover (which he said had been cleaned up to hide a problem). He traced the source to one of the big black capacitors - he replaced it. He then checked the voltages on the transformer taps - all were good except the 12.6v lead used for the pilot lights and tube heaters. That lead only showed 11.5 volts. When he turned on the heater switch the voltage on that lead went to zero volts. The heater switch seems to test ok. I suspect I am in possession of a badly modified TS830.

I have been searching the web and found numerous citations of problems associated with a QRO modification of the 830 but cannot find an accurate description of the modification. I am hoping to find it so that we can use it to find out if this radio has indeed been modified. And, if modified , put it back to its original specifications.

Also, I would appreciate any guidance from someone familiar with the TS830 internals.

Thank you in advance for any assistance given.

Mike

Hello Mike,

Your tech found traces of "varnish" on the inside of the bottom cover. He said he traced the source of the varnish to a big black capacitor.

I assume the big black capacitor your tech is talking about is one of two 100ufd 500VDC black electrolytic capacitors that mount on the chassis using round clamps, directly behind the VFO. Is this correct?

One additional comment.

Lets not jump to conclusion you have purchased a badly QRO modified 830 just yet. Lets look at a few more things first before making that determination.

Where on the bottom cover is the "varnish" stain located? Is the stain directly below the 2 HV filter capacitors? The 2 HV filter capacitors are directly behind the VFO, between the power transformer and the VFO.

Thanks both Dana and Mike it is the Rectifier Unit. I will check and replace if needed. All ive got to say for my self is Duh! As I have seen that picture numerous times while on Kens site.But when doing the work it could not come to me at all. So Thanks again for the help and quick reply. You Guys are the best. And maybe later I will come up with a challenging question.

I have MC-50, MC-60 and Shure 444. In each one I have replaced the cartridge with Heil HC-5 (I tested the HC-4 cartridge too).

In my opinion the HC-5 is the best for all around.

Kerry -

I use my D-104 with my Kenwood Twins. Everybody says I have great audio. I did take out the amplifier and add the the Heil upgrade kit to it though so it's really not a D-104 any more. But if you like the style of the D-104 and the performance of Heil then that's a good way to go.

Well it sounds like I should just keep the MC-50 and go with that. I will just put the D-104 up on the shelf for now right next to the Tuner +3 I have from my 11m SSB days. That is unless someone has a TR7400 they would like to trade for the D-104.

Hello Mike,

If the filament winding of your power transformer is really open BUT all of the other voltages, that is +800 +300 -150 (no schematic, only memory) are OK, you can always go the cheap way and find an external 12.6 volt transformer with enough amperes to do the job. It has to warm both 6146, the 12BY7A and the pilot lamps, easy to figure how many amps are needed. Simple low voltage connectors and wiring. Maybe you can use the blower power plug to feed it.

But, before giving away with your Xformer, check the wiring for cold solder joints, etc.. quite common with oldies.

Hope it helps.

Good luck & 73's - Daniel, ON5PY

It's possible that there is a short somewhere else in the radio. If you measure across the heater terminals of the PA valves, does it seem "reasonable"? Try hooking a car sidelamp bulb across the heater winding with the rest of the heater circuit disconnected (ie. only powering the bulb) - the 5W load is a bit less than the load of one PA valve. If it fails to light that, the transformer is stuffed.

Usual caveats and warnings about not SKing yourself with the 800V supply, etc.

21854. TS-830S-low output/no indication of ALC on 10 meters

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-23 01:20:06 UTC
From: Jim McPhee
Topic: 21843 Message: 21854

Good evening:

I continue to have issues with the TS-830s that I bought about two months ago. I have yet to make a contact on 10 meters, the only phone band available to me with my Technician class license.

Question/issue:
No ALC level at all when tuning the transmitter on 10 meters. There used to be, when I first got the rig, but not now. Output on 10 meters, according to meter on the MFJ-949 that I use for the dummy load, is about 50 watts. Output on other bands, is 100 watts or close to it.

Background:
I bought the TS-830S off ebay from a ham. He indicated that although it was a backup rig that received little use in the 10(?) years that he had owned it, and that he used it to make contacts prior to putting it up for sale.
Output was low on 10 meters when I got it, so I invested in matched pair of 6146Ws and a new driver tube.
I had it equalized by a ham gear tech near here in Albuquerque after my attempts appeared futile. (Already discussed on this forum.)
Output remained the same, about 80 watts according to the meter on the MFJ 949D that I was using the dummy load on.
It has appeared that the output was higher(80 watts) when the rig was recently turned on than when it had been on for a couple of hours (50 watts).

Current status:
When tuning up the xmitter for 10 meters now, 28.375 specifically, there is virtually no meter movement with the meter set to ALC. This is regardless of where the carrier control is set.

ALC "used to" show significant strength on 10 meters.

Output on 10 meters has diminished to about 50 watts, or a little below.

ALC continues to show significant strength on 20 and 12 meters, when I tune-up on those bands, just for comparison. Output into the dummy load on those bands is about 100 watts.

I've installed the following from Ken Kemski, K4EAA:
High-Voltage repair
Final Cage Partial Repair kit.
I have not yet installed Ken's "resistor kit for final repair" although I have it here .

I look forward to your responses regarding potential solutions for this problem.

Regards,

Jim McPhee

Hi Jim. 80 watts (CW) is about right for 10M with these radios. The tubes, especially the 12BY7a just do not operate as efficiently on 10M as they do on lower frequencies.

First, check the and replace (if necessary) the resisters. Then, check the 12BY7a driver tube. Usually 10M is the first band to show low output when the driver starts to go. using excessive ALC/mic gain can shorten the life of the driver tube. Always keep the ALC reading within the marked ALC scale when tuning up, and when operating.

BTW, the difference between 80 watts and 100 watts would barely (if at all) noticeable at the receiving station. To get an improvement of 1 S-unit at the receiving station, the transmitting station has to put out 4 times the power.

As to 10M, while there have been a few openings lately, it is still mostly dead.

Think you've pretty much nailed the problem there. If it's worse when hot, it does sound awfully like a resistor going high in value. Bear in mind that the high voltage section will be full of 20-year-old carbon comp resistors. These seem to be good at failing by going high in value, particularly when used with high voltages - old TV brightness circuit resistors spring to mind.

There was an interesting article about why metal film resistors are perfectly okay at RF in Radcomm this month - basically although they *are* a spiral of resistive material (and thus on the face of it they look like they'd be inductive) they have an inductance measured in nH at worst.

Hello to the group

Does anybody know what would be shorting out near Q5 on the RF unit or maybe Q5 is shorted or what would be causing a short ,I am noticing smoke coming from that area looks like the 0.47uf 50volt cap has been getting hot I replaced it but still doing it when the heaters are turned as well as crackling sounds heard in the receiver again ,only when the heater switch is on this time

Hello mike and the group

Mike my results as asked

AF! pin 1 9.01 volts
AF2 pin6 3.31volts

HV
800v on R/B actual 923volts
LV
300a ------335volts
300b ------334volts
14v --------14.15

210a --------255v
210b --------256v
STB ---------110v

BIAS SG

-C ----------115V
SG ----------113v

I am not sure what you make of it
The carrier unit and PLL unit was totally stripped pins checked look good to me under the magifier cleaned with crc and deoxit also all the connections the both relays pulled apart and carefully cleaned ,

I just like to add one more thing I did not tell you when replacing the duel smoothing caps before I tuned everything, I wired one the caps wrong way and burnt both rectifier caps but

replaced those and correctly wired 4x22 uf 450volts smoothing caps would this cause a problem ,well it caused me a headache,
I also replaced the 4 diodes d8-d10 because I was only getting 12.70volts on the af-avr unit the spec was saying between 13.5 to 15volt which seemed low but did not make much difference when replaced by 1n4004 diodes.

All I can say everything was working beautifully before I short circuited the rf unit onto the chassis

What do you make of it

Barry vk4baz

Martin,

Thanks for the response. This is actually the second 12by7a tube. I replaced it at the same time as the 6146Ws, and the fellow who did the equalization noted the low output, identified the driver as being the problem and replaced it as well. It does not appear that the driver is/was the problem.

The next thing I will do is replace the resistors. I have them, so I might as well replace them and eliminate them as the source of the problem. I understand what you said about the difference between 80 and 100 watts. I'm not too concerned about getting the 10 meter output higher than 80 watts. I just want to get it back to where it was when I got the rig, which was 80 watts or a little above.

Subject: Re: [TS-520_820_530_830] TS-830S-low output/no indication of ALC on 10 meters

Hi Jim. 80 watts (CW) is about right for 10M with these radios. The tubes, especially the 12BY7a just do not operate as efficiently on 10M as they do on lower frequencies.

First, check the and replace (if necessary) the resisters. Then, check the 12BY7a driver tube. Usually 10M is the first band to show low output when the driver starts to go. using excessive ALC/mic gain can shorten the life of the driver tube. Always keep the ALC reading within the marked ALC scale when tuning up, and when operating.

BTW, the difference between 80 watts and 100 watts would barely (if at all) noticeable at the receiving station. To get an improvement of 1 S-unit at the receiving station, the transmitting station has to put out 4 times the power.

As to 10M, while there have been a few openings lately, it is still mostly dead.

Gordon,

Thanks for the input. I will replace those resistors first chance I get and will report back on the results. May have to wait for next weekend when I have the time to get it done.

Daniel, my idea also. In the Heathkit eBay listings, there are always a few of the DC regulated
supplies listed for just a few dollars. True, it is much larger than simple transformer, but they
several advantages, DC filament voltage, (No AC Noise), easily selected current supply, and not any
ripple in the DC.

Jim, I looked through you emails about the this problem and I did not notice any mention of you
checking the band switch coupler. Do you still have the white plastic band switch couplers? Check
them for cracks. Cracked couplers will not let the band switch complete its connection. Most of us
automatically replace them when we get a 830S. I have two of them. If you are not actually tuning
in 10m, this could be your problem.

21868. Re: TS830 low voltage from transformer tap 12.6v lead

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-23 15:06:17 UTC
From: mmurphey2
Topic: 21843 Message: 21868

Yes. It was directly beneath the HV cap. He(elmer) replaced it with another of the same value, and tested it - ok. He then reported that he was able to get 20-40 watts out on several bands.

I purchased another 830s transformer (from a parts radio)from the internet and he tested it on the bench. It has the same symptom as the one in the radio - 12.6v lead shows good voltage until a load is placed on it - then it drops to 0-2 volts. Both transformers test good on the other leads.

Thank you for your reply.

Mike KI4WWG

I took it to him and he put it on his bench. He quickly found that it had no output on any band. He soon showed me the varnish on the inside of the bottom cover (which he said had been cleaned up to hide a problem). He traced the source to one of the big black capacitors - he replaced it. He then checked the voltages on the transformer taps - all were good except the 12.6v lead used for the pilot lights and tube heaters. That lead only showed 11.5 volts. When he turned on the heater switch the voltage on that lead went to zero volts. The heater switch seems to test ok. I suspect I am in possession of a badly modified TS830.

Subject: [TS-520_820_530_830] TS-830S tuning Rate

I know there is a Mod to change the tuning rate on a VFO-230, but is there a Mod to slow down the tuning rate on a TS-830S internal VFO ?

Thanks,

Gordon

Hello Mike,

The "varnish" stain your elmer pointed out to you appears to be caused by the HV filter capacitor leaking. The leakage could have been caused by an inexperienced operator pushing the final amplifier too hard resulting on excessive stress placed on the HV power supply and supply component, i.e., filter capacitors etc.

When excessive stress is placed on the power supply, heat builds up inside the filter capacitors. With heat building up inside the capacitors, pressure inside the capacitor is produced. If the heat is not reduced then the bottom seal on the capacitor(s) can easily rupture or the capacitor(s) can explode. If the seal ruptures, the internal compounds leak out onto the surface of the surrounging chassis or, in this case, on the inside of the bottom cabinet.

You said your "elmer" replaced the bad capacitor. Replacing one capacitor can make the radio work again. However, "if" the remaining original capacitor has high internal leakage current, the original capacitor will cause undue stress to be placed on the new capacitor. Checking the remaining original capacitor is warranted here especially since there is evidence of one HV filter capacitor has physically leaked onto the inside of the bottom cover!

If the remaining original filter capacitor has low or equal leakage current compared to the new capacitor, only after checking the capacitor with a capacitor checker, then there is no need to replace both. However, having said that AND since the remaining original capacitor is old and most likely will not have the same leakage current as the new capacitor, I recommend replacing "both" capacitors. This is the safe route to take. Ken, K4EAA, sells a complete replacement kit. See his website, www.k4eaa.com for further details.

With the heater switch OFF and the power switch is turned ON the dial and meter lamps will glow. Turning the heater switch ON the dial lamps should remain at the same brilliance as the lamps were when the heater switch was OFF. If the lamps glow the same with or without the heater switch ON then the filament windings are good. If the filament windings were shorted, the tube's filaments would not light up and the dial lamps would not glow, with or without the heater switch turned on. The tube filaments AND dial lamps are powered from the same secondary winding of the transformer. I also suspect the fuse would blow when power is applied to the 830 if the 12.6VAC windings were shorted.

I also recommend checking the final tube cathode resistors, R2 thru R5. These are mounted on the bottom of the final amplifier PC board. Each resistor is 20 ohm 1/2 watt. The resistors are wired in parallel which results in a total resistance of "5 ohms". If one or more of these resistor's values change, normally resistors increase in resistance, the IP current flowing through the final tubes will change and can easily result in lower output.

If, during checking R2 thru R5, one or two of the resistors have increased in value, change ALL 4 of the resistor, not just the bad ones. Visually inspect each resistor for signs of discoloration or cracks due to overheating. You should use a magnifying glass so minor cracks can be seen. I have seen these resistors visually look "good" but, a closer inspection with a magnifying glass, clearly show the bodies of the resistors were cracked. Resistors are cheap, less than a dollar, so it's good insurance to replace them all.

The same goes for the filter capacitors, changing both is simply good insurance. There are other capacitors that should also be checked on the IF UNIT board and other places. However, at this point, I would at least check and replace as necessary R2 thru R5 and both HV filter capacitors with "new" capacitors and resistors.

From: jmcphee@comcast.net
Topic: 21843 Message: 21871

Jerry,

Thanks for the suggestion.

It does receive in 10 meters, and the mfj auto tuner that I bought used recently does indicate the same frequency on it's readout as the 830 does on it's. I'm confident that the band switch is completing the the connection.

It does still have the white plastic couplers, but I have checked them while rotating the switch and did not see any cracks or any flex in the coupler.

Jim, I looked through you emails about the this problem and I did not notice any mention of you
checking the band switch coupler. Do you still have the white plastic band switch couplers? Check
them for cracks. Cracked couplers will not let the band switch complete its connection. Most of us
automatically replace them when we get a 830S. I have two of them. If you are not actually tuning
in 10m, this could be your problem.

Topic: 21843 Message: 21873

Hello Jim,

First, purchasing matched pairs of final tubes is a waste of money.
There is no benefit by using matched pairs of final tubes. Matched
tubes "should" be used in "push-pull" amplifiers. The final amplifier
in the 830 operates in "parallel" not "push-pull".

I am going to assume you have check and, if necessary, set the final
amplifier's 60ma idling current as outlined in the 830's operating
manual. This should be checked and, if necessary, set to 60ma, again
as outlined in the operator's manual.

I seriously doubt the problem is related to the band switch
coupling in the final amplifier. If that were the case the
problem would be more than likely be evident on all bands as
the band switch coupling would slip causing the final band switch
wafer to improperly align on each band.

I suspect the final amplifier is not neutralized properly.
A properly neutralized final amplifier will have maximum output
occur at the same time the final amplifier's IP current reaches
maximum dip. Neutralize the final as outlined in the 830's
operator's manual.

I also recommend performing a complete cleaning of the final
amplifier. This includes cleaning the PLATE and LOAD variable
capacitors using contact cleaner on the variable capacitor shaft
to capacitor frame connection. Use canned air to remove any/all dust
and dirt from these connections plus dust and dirty in the final
amplifier cage itself. Also, use contact cleaner to clean the band
switch wafer in the final amplifier cage plus all the other band
switch, MODE, and FUNCTION switch wafers as well. Again, use canned
air to remove any and all dirt, dust, and excess contact cleaner.
Wait 3 to 5 minutes before applying power as contact cleaner is
"flammable" and it only takes a small spark to ignite it!

Hello Ray,

No, you do NOT need an external relay box/interface to connect
the 830 to the AL-811H amplifier. The 830's internal relay can
easily handle the 12VDC 100ma AL-811H relay switching voltage.
There are very few amplifiers produced today that have high
amplifier relay switching voltages. There are two amplifiers
that I know that have high relay switching voltages and they are
the Heathkit SB-200 and SB-201. I'm not sure about the
Kenwood TL-922 but I believe the 830's relay contacts can easily
handled the TL-922 amplifier relay switching voltage.

You will need a matching DIN plug to make the connections to the
ACC socket on the rear of the 830. Consult the 830's operator's
manual, page 25, for further details on connecting the AL-811H's
ALC and RELAY connections to the 830. Use shielded cable to make
these connections. Cheap stereo interconnecting cable will do fine.

Take the time to read and fully understand the tune up procedures
outlined in the AL-811H manual as well as the 830's manual. If you
have the slightest doubt, read the manuals again and check the wiring
to be sure. Never assume anything!

Great, it would have been a heart breaker to have worked a dozen issues only to find that the band
switch coupler was slipping.

Good luck,

Jerry, KE5PUT

does the dg5 have a regulator circuit inside, maybe that is where the smoke
came from, causing the 520s to be on a shorted circuit (and overheating).

The DG-5 has an internal 7805, 5V, regulator that provides
5VDC to the TTL logic circuits. There is also the analog power
provided by Q31 and zener diode D17. Zener diode D17 sets Q31's
base voltage. Q2 controls the 4.5VDC LED voltage. All 3 of these
voltages are produced from the 13.5VDC provided by the 520S/520SE's
13.5VDC power supply available on the rear panel of the 520S/520SE.

I doubt the 7805 regulator caused the smoke. More than likely
one of the resistors in the power circuits caused the smoke due to
a failed diode, transistor, or both.

See the DG-5 service manual, page 23, for further details on the
power circuit.

Hello Eric,

Since your symptoms are the same in transmit and receive, full
scale s meter in receive and full scale (ALC position) in transmit,
I suspect a bad/loose ground/mounting screw(s). It also could be
a bad connection on one of the IF UNIT plugs. Remove and re-seat
all plugs to each PC board. Do one plug at a time.

Check all board and chassis ground screws to ensure they are
tight.

I doubt the problem is a voltage issue since the problem is not
causing a loss of receiver sensitivity nor is it causing a
reduction in RF output in transmit mode. You simply have a full
scale meter in transmit (ALC position) and full scale S meter in
receive.

Hello Group
Following Mike,s remark

There are two amplifiers
that I know that have high relay switching voltages and they are
the Heathkit SB-200 and SB-201.

There is also the Alpha 76 which has 25V on the relay line and I almost
fried a FT 757 by not using a relay box
between them. Now I have built a small relay box which workes fine.

Subject: [TS-520_820_530_830] Re: need help..

Hello Ray,

No, you do NOT need an external relay box/interface to connect
the 830 to the AL-811H amplifier. The 830's internal relay can
easily handle the 12VDC 100ma AL-811H relay switching voltage.
There are very few amplifiers produced today that have high
amplifier relay switching voltages. There are two amplifiers
that I know that have high relay switching voltages and they are
the Heathkit SB-200 and SB-201. I'm not sure about the
Kenwood TL-922 but I believe the 830's relay contacts can easily
handled the TL-922 amplifier relay switching voltage.

You will need a matching DIN plug to make the connections to the
ACC socket on the rear of the 830. Consult the 830's operator's
manual, page 25, for further details on connecting the AL-811H's
ALC and RELAY connections to the 830. Use shielded cable to make
these connections. Cheap stereo interconnecting cable will do fine.

Take the time to read and fully understand the tune up procedures
outlined in the AL-811H manual as well as the 830's manual. If you
have the slightest doubt, read the manuals again and check the wiring
to be sure. Never assume anything!

Subject: [TS-520_820_530_830] Re: TS-830S-low output/no indication of ALC on 10 meters

Hello Jim,

First, purchasing matched pairs of final tubes is a waste of money. There is no benefit by using matched pairs of final tubes. Matched tubes "should" be used in "push-pull" amplifiers. The final amplifier in the 830 operates in "parallel" not "push-pull".

I am going to assume you have check and, if necessary, set the final amplifier's 60ma idling current as outlined in the 830's operating manual. This should be checked and, if necessary, set to 60ma, again as outlined in the operator's manual.

I seriously doubt the problem is related to the band switch coupling in the final amplifier. If that were the case the problem would be more than likely be evident on all bands as the band switch coupling would slip causing the final band switch wafer to improperly align on each band.

I suspect the final amplifier is not neutralized properly. A properly neutralized final amplifier will have maximum output occur at the same time the final amplifier's IP current reaches maximum dip. Neutralize the final as outlined in the 830's operator's manual.

I also recommend performing a complete cleaning of the final amplifier. This includes cleaning the PLATE and LOAD variable capacitors using contact cleaner on the variable capacitor shaft to capacitor frame connection. Use canned air to remove any/all dust

and dirt from these connections plus dust and dirty in the final amplifier cage itself. Also, use contact cleaner to clean the band switch wafer in the final amplifier cage plus all the other band switch, MODE, and FUNCTION switch wafers as well. Again, use canned air to remove any and all dirt, dust, and excess contact cleaner. Wait 3 to 5 minutes before applying power as contact cleaner is "flammable" and it only takes a small spark to ignite it!

I would check and clean all the connectors on the IF board.
The 820's are Famous for the springy part of the terminals in the
plastic connectors breaking.
Check carefully for that problem.

21888. Can't seem to align speech processor correctly on TS-820S

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-25 04:04:15 UTC
From: Bill Crowell
Topic: 21888 Message: 21888

I think I aligned the speech processor on my TS-820 exactly as instructed in the Kenwood service manual, but I get much less drive and plate current with the speech processor turned on than with it off.

I was wondering if anybody might know what could cause this.

Does it matter whether I'm using an MC-50 mic or an MC-35 for the speech processor alignment?

21889. low sensitivity in ts510

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-25 15:15:56 UTC
From: oz1bxn
Topic: 21889 Message: 21889

Ts510 has bad ears at 20meter and up .
I try to change the V204 6BZ6 RF amplifier , this helped a tiny bit .However this was just another old tube I had . Would it help to buy a new 6BZ6 ?

Has anyone a mods for improved sensitivity in ts510?

From: hotfoot95404
Topic: 21819 Message: 21890

When I'm transmitting cw, sometimes the sidetone will change in pitch and then settle back to normal.The other station will report that my frequency will jump slightly at times.Listened on my receiver and confirmed that it jumps about 10 percent of the time Sometimes when the sidetone isn't acting up. The jump is about 20 to 30 hz Checked the relay and it seems ok.Anyone run across anything like this? 73

Hello Pete,

If this happens in transmit it more than likely also happens in
receive.

I suspect the variable capacitor shaft to capacitor frame contact
in the VFO is dirty. Clean this "pivot" point with contact cleaner
and use canned air, Walmart sells canned air in large cans, to remove
the dirt and excess contact cleaner.

Hello Chris,

Your problem appears to be either old weak tubes, an alignment
problem, or both.

You should only replace tubes that test weak.

You should only perform an alignment when all tubes have been tested
and weak one replaced. Never attempt an alignment if there are weak
tubes in the radio otherwise you will be redoing the alignment
later when you replace the weak tube(s).

If you do not have the operator and service manuals, you can download
them free at N6WK's website:

http://www.n6wk.com/kenwood/

Topic: 21888 Message: 21893

Hello Bill,

The 820 requires a high impedance microphone.

The MC-50 is a high impedance microphone and will work fine with
the 820.

The MC-30 microphone, however, is a "low impedance" microphone and
will not work properly with the 820.

I would go back over the alignment procedure again, ensuring that
each adjustment step produces the desired result. If the desired
result is not produced then you would have to determine why before
proceeding to the next step.

I would check the 9VDC and 3.3VDC supplies to ensure they are
correct. These supplies are on the AF UNIT and the check and
adjustment steps are at the beginning of the 820's alignment section
in the service manual.

Hi Mike
Well yes thanks. I take that I should be able to "hear the band" when I plug the antenne in, even on 10 . and changing the Tube with another old one , did some improvements . The rig works great on 80 , it just going up bands and sensitivity drops . Alingment should be fairly ok . So new tubes :-)

21897. Problem with TS-830 RIT

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-26 01:14:17 UTC
From: steveb84us
Topic: 21897 Message: 21897

I received this e-mail from a fellow TS-830 owner. I thought I would post his problem here and see if anyone has any ideas of what to look for.

Thanks in advance.

Steve - N9SB

I bought a TS 830 a little over a year ago, I must say, the more I use it, the more I like it.

I don't know if this is normal or not, but the RIT control seems to be acting up. When you first turn the radio on, and you press the switch, the red light comes on, and the knob seems to function normaly. But, after the radio is on for awhile, the frequency setting that you have made with the control will freeze up. I have turning off the RIT, and back on again, and it will still remain non functional, even with the red light on. If the radio is turned off for awhile, and then you turn it back on, then it will work.

It sounds to me like a component tempature issue. Also, the NB control has never seemed to work on my 830, and 820 both. Any ideas of what is happening? If you can't answer these question, please feel free to foreward it to someone who can help.

Thank you for the help and advice that you have given me in the past.

Yep you're right Dave. The MC-35 is a high impedance microphone. My mistake.

Hi Chris,

Another weakness is that the 1st xtal oscillator output drops as frequency raises, so lower injection voltage in the 1st rx mixer and 2nd tx mixer - I had this joke with a TS-515.

To test tubes, measure the various voltages, especially cathode voltage for penthode tubes such as 6BA6, 6AU6, 6BZ6. That's how I worked with B/W TV sets many years ago. Testmeters are not always reliable.

Thanks to Mike and Dave for your replies. I was able to restore the digital display by doing the following. First, I believe that Dick is correct and one of the power resistors overheated causing the smoke. I replace the rectifier diode, D18, and also discovered by tracing the circuit a short following the output of the 7805 regulator. The short was corrected and then I got two decimals in the display. Cleaning the RCA jacks for the Het and VFO outputs (in the TS-520S) and inputs (DG-5) fully restored the display. Thanks again for your help.

21901. TS-520 IOTA success!

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-26 22:59:47 UTC
From: Gordon JC Pearce
Topic: 21901 Message: 21901

Well then, that's me home from IOTA. This year our club pitched up on my croft on the Isle of Skye - two stations in a caravan and a tent, powered by a generator. If you worked GM4AGG or GM7WOS, you worked us ;-)

I brought my TS-520 along, and took the 20m 1/4 wave vertical I use down here in Glasgow. I set these up on the Friday night and fired it all up just to check that the radio had survived the trip, and was almost immediately rewarded with a QSO with K1GUN in Maine on 20m and AA2KB in New York on 40m when I flung the loading coil on.

The "other" (okay, main) station used a fairly modern rig and MFJ autotuner into a delta loop - "our" station used an MFJ-949 and a full-size G5RV driven by my TS-520. We're not particularly hardcore contesters, so 111 contacts for the "backup" station wasn't too bad.

"Okay", I hear you all say, "but what about the TS-520?" Well, it performed more-or-less faultlessly on 3.5, 7, 14 and 21 although it seemed reluctant to transmit on 28MHz and when hooked up to a reasonably accurate power meter it wasn't putting out any more than about 70W. Time to check and change those screen grid resistors I think. The radio was powered up for pretty much the whole 24 hours (we unplugged the generator cable leading to that tent to re-route it to avoid puddles - fairly heavy rain this morning clearing to 40-50mph winds and bright warm sunshine by lunchtime, a typical Scottish summer). Looking at the log it was active pretty solidly on 7MHz for four hours at one point.

So, what now? Well as I said, I want to get the low output power sorted out and track down the lack of 28MHz. Maybe the reason 10m has seemed so dead here is that my radio is just plain not working on that band. I'm planning a trip up north next weekend too, so if I'm up there and if I have time I'll be active on 80m

Gordon 2M0YEQ

21902. incorrect displayed frequency

I see these messages go by, and also searched the old messages and tried to find my answer, but no luck (unless someone can direct me to the correct message number)

I have a ts820s, that operates just fine, except for the digital display. for example the digits are showing 162 3.3 where i am actually on 14.080.0 (or close to it), copying rtty,

check the avr unit, although with the display being on, did not think there was a problem, 14v in 4.78v out

suspect counter unit, do I have to pull it, or can I check pins??

Hi Daniel , yes you are right on the Xtal osc , 40m is max and 20 15 10 is only half for this voltage .
By checking the cathode voltage ,good point to see if the tube is pulling some current . Hm , I still would like to get me a new NOS 6BZ6 :-)

21905. TS-820S parts to go..!

Yahoo group: TS-520_820_530_830 (2009)
Date: 2009-07-26 23:54:34 UTC
From: pissousky
Topic: 21905 Message: 21905

Hello guys,I am not here as a business but I thought that someone might need parts for whatever repairs so I tought I would offer them to the group first...I have a TS-820S here that I used the power transformer for another radio...All the boards,af-avr-rf-if-pll-vox-rectifier-HV-rotary switches-ect.. so as coil pack with band switch,relays,display,meter,knobs,driver and finals,etc...are in great working order,tell me which part you need and I'll give you a price....thanks (email:erpi1182@...)

21906. ATTN: KJ4GXN [TS-520_820_530_830] amazing

Is the ts130se complete Harlan ?

Thanks ,

Charlie , W5COV

I assume your 4.78VDC output was measured on pin 1 of the 5V-AVR UNIT mounted on the tall stand-off next to the IF Unit board. This provides the 5VDC for the Counter Unit. The Counter Unit also requires 14VDC on pin 4 of the bottom edge connector on the bottom of the Counter Unit.

You might try cleaning the bottom edge connector on the bottom of the Counter Unit along with the Counter Unit's protruding edge connection on the bottom of the Counter Unit itself. Also clean the multi-pin connection and plug on the top of the Counter Unit and check all mounting screw holding the Counter Unit and DG-1 display tube mounting screws to the chassis and mounting brackets to ensure they are tight.

Sorry I meant that Mike (not Dick) was correct as to the source of the smoke! 73s, Scott, N6CIC

>
> Thanks to Mike and Dave for your replies. I was able to restore the digital display by doing the following. First, I believe that Dick is correct and one of the power resistors overheated causing the smoke. I replace the rectifier diode, D18, and also discovered by tracing the circuit a short following the output of the 7805 regulator. The short was corrected and then I got two decimals in the display. Cleaning the RCA jacks for the Het and VFO outputs (in the TS-520S) and inputs (DG-5) fully restored the display. Thanks again for your help.

21909. Re: DG-5 Failure

Congratulations Scott on fixing your DG-5. I'm sure you have a feeling of accomplishment and rightfully so! It is always good to hear that hams, like yourself, are able to fix their own gear. That's how we ALL learn.

I use to own a TS-520SE with a DG-5 quite awhile ago. Ran it on RTTY using a home made terminal unit, tone modulator/demodulator, I built into an old military VTVM plastic case. I used an old TRS-80 Model 1 computer running TRSDOS and my own designed Z80 assembly language software. As many old timers know who use them, the TRS-80 Model 1 generated a lot of RF computer noise. The RF noise could be heard quite a distance from the computer and that's what prompted the Radio Shack to correct the problem which they did, sorta, by bringing out the TRS-80 Model III followed by the Model IV and Model 4P. The Model 4P was a great computer for its time. I had one and programming in assembly language was much simpler especially with the various RST interrupt calls.

RTTY ragchewing was a lot more active on a daily basis back then, then it is today. In comparison, RTTY was as active back then as PSK is today. PSK wasn't even heard of back then. I still get on RTTY now and then with an old AEA PK-232MBX and home made Visual Basic 6 software. Oh well, things do change over time.

Hard copy was on a Teletype Model 28 KSR I built up from scratch, I was a teletype repairman in the Navy for 17 years. Had a lot of fun back then.

Again, Scott, congratulations and enjoy the DG-5 and TS-520S.
